I confess that I am loth to operate on this patient again; first, because the quantity of blood lost is not great, and is apparently diminishing; and secondly, because in operating on these cases one is, as it were, groping in the dark, with no recognisable lesion presenting itself for rectification. How often in operating on kidneys do we find adhesions when there has been no hæmaturia? I cannot say that the evidence in favour of adhesions producing hæmorrhage is sufficiently conclusive, although, I understand, some such view is held by no less an authority than Professor Rovsing, who operated on this case. In discussing painless or symptomless hæmaturia, Mr. Hurry Fenwick(*a*) refuses to accept the terms "local hæmophilia" or "angioneurosis" as applicable or warrantable, and quotes Rovsing as pointing out that a distinct pathological change is present in most of the cases. He divides his own cases into five groups, as follows:—(1) Chronic granular kidney; (2) angioma, or capillary nævus of a renal papilla; (3) benign or malignant growths of kidney or ureter; (4) rare cases of embedded aseptic calculus; (5) submucous deposit of crude tubercle. It appears likely, therefore, that according to this classification the case before us would be considered as one of chronic nephritis in an early stage. Casper(*b*) says, "It has not been determined whether there is a local renal hæmophilia or bleeding from healthy kidneys." He also mentions that it is well known "that severe hæmorrhage may occur in chronic nephritis." He does not consider the existence of angioneurotic bleeding as proved. My own experience would lead me to the conclusion that not only is hæmaturia a fairly common occurrence in chronic nephritis, but that it may occur simultaneously on both sides. I have recently examined three such cases, and seen blood-stained urine issue from *both* ureters. I will reserve the further discussion of these cases for a future occasion.

The case I have just shown you is a good illustration of the difficulties attending a diagnosis, even when such accurate aids as cystoscopy and ureteral catheterisation are available.

With regard to treatment, I propose, in the first place, to try the effect of drugs such as ergot for some time. If the bleeding still continues, the question of operation will then arise. I have seen hæmaturia, presumably of this type, entirely cease after the kidney has been explored by palpation and incision, but the exact way in which this desirable result has come about is not very clear. Mr. Fenwick believes that the hæmorrhage issues from the lower calyces, and invariably cuts through the calyces of the lower half of the kidney. He also thinks fixation of the kidney is an important element in preventing a return of the hæmorrhage.

BACTERIOLOGY AS IT AFFECTS GENERAL PRACTICE.

By S. J. ROSS, M.D., Ch.B.,

Assistant Surgeon to the Bedford County Hospital.

A knowledge of bacteriology is essential for correct diagnosis, and also for successful treatment. I wish to illustrate these points by notes of some cases which have come under my notice.

Firstly, let me take examples of streptococcic poisoning.

I saw a patient who had been recently confined, who, on the fourth day after her confinement, had a rigor, and the uterine discharge lessened, and became offensive. Temperature 140°, pulse 130. I took away some of the discharge, and discovered that the offending organism was a streptococcus. I injected 30 cc. of antistreptococcic serum, in 3 doses of 10 cc. each. After the first injection the temperature fell to 101°. After the second injection the temperature fell to 99°; and after the third injection the temperature became normal, and the patient made an uninterrupted recovery. Locally, intra-uterine antiseptic douches were given; but these had been given three days before I saw her, and yet the patient was going steadily downhill; and, therefore, we can conclude that the serum saved the patient's life, as she began to improve after the first injection, and improvement followed each injection.

A female patient, æt. 45, had an attack of follicular tonsillitis. A throat sweep proved the presence of streptococci in large numbers, and staphylococci and microccoci. Now this patient was the subject of endocarditis of the mitral valve of 20 years' standing. Four days after the throat trouble was better she had a rigor, and her temperature rose to 104°. She subsequently developed septic thrombosis of her left femoral vein, and abscesses in both sterno-clavicular joints, and abscesses in both forearms, and finally, gangrene of the left leg. Doubtless she had an infective endocarditis. Her blood yielded streptococci, and also pus from one of the forearm abscesses. The origin, doubtless, was from the septic throat. My only regret in this case was that she refused serum treatment.

I saw a boy, æt. 12, with a discharging left ear, originating from an attack of scarlet fever. Examination of the pus proved the presence of streptococci. He complained of severe pain, and had some redness and œdema over his left mastoid. His mastoid was trephined, and a mastoid abscess evacuated. I mention this case to draw attention to the fact that a streptococci ear infection is the most virulent and dangerous infection with which we can meet.

Staphylococcic Infection.

I saw a youth, æt. 24, whose arms and forearms were covered with pustules. Examination of the pus proved the infection to be staphylococcic. I mention this case merely because it was at once suggested to me, Why not inject antistreptococcic serum? My answer was—It is useless to inject this serum unless we are sure that the offending

(*b*) "Genito-Urinary Diseases." Edited by Bonney. P. 530.

organism is the streptococcus, or that streptococci are the predominating organism in the discharge.

Diphtheria Bacillus.

A boy, æt. 12, was brought to me on account of weakness in his legs, and an external strabismus. I inquired if he had had a sore throat recently, and his mother said, "Yes." Five weeks previously he had had a bad throat, but it was well in three days. I took a throat sweep, which yielded a positive result. Streptococci, staphyloccoci, and Klebs-Loeffler bacilli were present. He was isolated, and kept in bed for three weeks. Iron and strychnine were administered internally, and his recovery, as is usual in such cases, was complete.

Pneumonia.

A youth, æt. 20, and with a marked tubercular history, after a long cycle ride in a drenching rain, developed a left pneumonia, the whole of the left lung being solid. I examined his sputum, and readily demonstrated the presence of the pneumococcus. Crisis, however, never occurred, his temperature became very irregular, and I carefully overhauled him for empyema. There were, however, no signs of fluid in the chest. The character of his sputum changed, and became typically nummular. I again examined his sputum, and discovered tubercle bacilli. He developed acute tuberculosis, and died.

Mixed Infections.

I attended a youth, æt. 24, for pulmonary tuberculosis. When I first saw him, the disease was very advanced. His chief complaint, however, was not of cough, as so frequently happens, but of intense thirst and intolerable heat. His temperature was 104.6°. I examined his sputum and found tubercle bacilli and streptococci. I injected 10 cc. of antistreptococcic serum. The temperature fell to 101°, and the patient fell into a sound sleep, from which he awakened greatly refreshed. I repeated the injection with most gratifying results; and the patient, in the last stages of this most distressing disease, at least was rendered comfortable. I think many cases of phthisis might be benefited by the use of serum, when evidently we have asssociated with the tubercle bacillus septic organisms, and such organisms are proved to be streptococci, or streptococci predominate.

I was called to see a young man, æt. 24, who came from a very tubercular stock, on account of rapid emaciation and dysuria, and frequent micturition. He was evidently in the last stages of pulmonary pthisis. He had a large cavity at the apex of his left lung, and crepitations over the whole surface of both lungs. I examined the urinary deposit, and discovered tubercle bacilli. This proved to my mind two facts: (1) that he had tubercle of the bladder; (2) that the tubercular deposit was extensive, and breaking down. I say extensive, because repeatedly I have examined urinary deposits in cases of undoubted vesical tubercle, and have failed to isolate the organism. I think this difficulty arises chiefly from the fact that very clear symptoms of vesical tuberculosis are often present, before the tubercles have broken down, and until they have broken down we cannot expect to discover the organism. To return to our case. Operative interference was out of the question. Urotropine rendered the local condition tolerable for the three weeks which he survived after I first saw him.

A young man, æt. 19, sought my advice, on account of swelling of both knee-joints. The joints were distended with fluid, and I naturally suspected a blood infection. I asked him whether he had any urethral discharge, and he replied "No"; but as I have learned that my patients' words are not always reliable, especially upon questions of morality, I examined which I suspected was the offending organ, and found a tell-tale drop, which, received upon a cover slip, duly stained, revealed the presence of the gonococcus. I reminded my patient that we were more scientific now than we were 20 years ago, and could say with certainty, with the aid of the microscope intelligently employed, "You have sinned!" So he acknowledged the power of accurate scientific knowledge, and fully confessed his shortcomings.

These few cases out of many I could cite will prove the value of an ordinary knowledge of bacteriology—a knowledge which any general practitioner, really interested in his profession, may readily acquire.

I may add that, for staining ordinary organisms, methylene blue is generally most suitable. For staining tubercle bacilli, I always adopt the method taught to me by Kanthack. I stain the specimen in carbol fuchsin for five minutes, and then wash it and dry it with blotting paper; decolorise it with 1 in 4 nitric acid, wash and dry, then stain with methylene blue, wash and dry. The tubercle bacilli are stained red.

It appears to me to be the height of folly to grope in the dark, when light is so easily obtained. It is most unscientific to diagnose a diphtheritic throat. A patient has either diphtheria, or not. There is no intermediate state; and it is unwise to wait until soft palate paralysis and weakness of the legs, or other paralytic symptoms become manifest, before we make a definite diagnosis, or until that most tragic event happens, a sudden heart collapse ending fatally.

Great doubts have been repeatedly expressed as to the value of antistreptococcic serum. I think these doubts arise from an injudicious use of the serum. A high temperature, and other evidences of sepsis, lead the unwary to employ this serum in the hope of ameliorating the patient's condition, but antistreptococcic serum will not benefit the patient if he is suffering from staphylococcic poisoning. We must examine the discharge to discover the offending organism. If it be a streptococcus, then we can employ the streptococcic serum, and feel confident that benefit will arise from its employment. My experiences are not in any way unique, but I hope these notes may prove to any general practitioner who has not interested himself in bacteriology, that great help results from its employment in every-day work, and that the process of staining specimens is easy, and the recognition of organisms is a gift easily acquired. I may add that the growth of organisms upon media, and the recognition of their characteristic appearances are also easily learned.

OUT-PATIENT'S ROOM.

ROYAL FREE HOSPITAL.

Carcinoma of the Breast.

By Mr. JOSEPH CUNNING, B.S., F.R.C.S.

Amongst Mr. Cunning's out-patients was a woman, æt. 69, rather stout, but otherwise healthy-looking, who complained that she had noticed a lump in her breast for twelve months, but as it had given her no pain till recently she had not sought advice about it. The routine method of examination in all cases of breast tumour was then demonstrated: first, inspection—attention was called to the difference in the level of the two breasts, the affected breast was shown to be on a distinctly higher plane than the other. This at once gave some indication that the disease of the breast was of a constricting nature, and the common disease of the breast which caused shrinking was, of course, scirrhus; so that, quite early in the examination, without touching the patient, the surgeon has some very important diagnostic information. On further inspection it could be seen that the skin was dimpled out over an area the size of a florin in the lower and outer quadrant of the breast. On palpation a lump the size of a tangerine orange could be felt below the dimpled area, which was attached to the skin and could not be separated from the breast substance. The lump was solid and fairly well defined. To find out whether it was attached to the pectoralis major, the arm on that side was raised above the head so as to put the fibres of the muscle on the stretch; it was then seen that the lump in the breast could not be moved along the course of the fibres. Mr. Cunning pointed out the fallacy of trying to establish this point by moving the breast tumours at right angles to the direction of the fibres, as this only demonstrated that the tumour was not attached to the thoracic wall. The axilla was then examined and one large hard gland felt below the border of the pectoralis major. The supra-clavicular region was free from enlarged glands. Nothing abnormal was found in the opposite breast or axilla, and finally the liver was examined, but no secondary growths were perceptible. With regard to the diagnosis, Mr. Cunning said that an inflammatory origin to this tumour could be left out of account owing to the length of time it had existed, and the fact of the growth being solid excluded any form of cyst; therefore, the diagnosis lay between simple solid growth and malignant growth. There were many reasons for putting out of account that the growth was simple: first, its infiltrating character, for, as had been pointed out at the examination, the tumour involved not only the breast, but also the skin and the pectoralis major. The gland in the axilla was of a densely hard nature, whereas, even if enlarged glands were present in connection with a simple growth, they would be of a softer nature. There was, therefore, no reason for doubting that the case was one of scirrhous carcinoma of the breast. The treatment Mr. Cunning would advise was an operation the principles of which were based on a knowledge of the anatomy of the breast and the direction in which its lymphatic vessels ran. As regards the breast itself, an important fact to remember was that the prominence of the breast gave no real indications as to the extent of the organ, for there were outlying lobules extending upwards nearly to the clavicle inwards to the margin of the sternum, downwards to the seventh rib and outwards to the middle of the axilla. A carcinoma, no matter in what portion of the breast, was in lymphatic communication with every part of the organ, and as the growth extended by permeation of these lymphatics, which extension could only be demonstrated microscopically, it was of the utmost importance that the whole breast, including the outlying lobules, before mentioned, should be removed. The second consideration was the arrangement of the lymphatics, the three important sets to remember being: first, the set running from the breast to the skin in the suspensory ligaments; these were present over the whole of the prominence of the breast, and for this reason all the skin in this situation should be removed; second, the lymphatics from the deep portions of the breast run to the axilla in the substance of the pectoralis major fascia, and for this reason the pectoralis major muscle should be removed; the third set of lymphatics comprised those running from the lower border of the breast to the peritoneum, and for this reason the incision should be carried down to the upper attachment of the rectus. The operation, therefore, should consist of an incision which surrounds the whole of the prominence of the breast; the skin should then be reflected over the whole of the limits of the outlying lobules, as described, then the fat, the breast, the pectoralis major muscle, the pectoralis minor, and the fascia lying underneath should be reflected outwards in one mass, with the exception of the clavicular portion of the pectoralis major. The apex of the axilla is thereby exposed and all its fat, lymphatic vessels and glands are detached in one mass from above downwards; it only remains then to sever the insertions of the pectoralis major and minor and the mass is free. In this way there has been no cutting across of lymphatic vessels in which there may be carcinomatous growth, so infection of the wound by malignant cells is avoided.

OPERATING THEATRES.

FRENCH HOSPITAL.

Kronlein's Operation for Orbital Tumour.—Mr. G. W. Thompson operated on a man, æt. 30, who had been admitted with a history of having been struck three years ago with a swagger cane in the neighbourhood of the inner canthus of the left eye. Gradual failure of vision had dated from two or three months after this period, and at the same time the eye became gradually proptosed. On admission the left eye was enormously proptosed forwards and slightly upwards and outwards. Movements of the eyeball were somewhat diminished in all directions. There was some œdema of the lower bulbar conjunctiva, and the patient was only able to close the eye with some difficulty. The eye itself was perfectly blind, due to advanced optic atrophy. No swelling could be felt in or round the orbit. No pulsation or bruits could be detected over the eye. The neighbouring sinuses and cavities appeared to be normal. The patient had already taken anti-syphilitics elsewhere. It was proposed to enter the orbit by Kronlein's operation. The man having been anæsthetised a curved incision was made along the outer orbit, starting just above the external angular process of the frontal and terminating just above the middle of the zygoma; the frontal portion of the malar bone was exposed, and a large portion of the outer bone wall of the orbit was chiselled through and wedged out, the orbital periosteum having been previously lifted up from the bone. After slitting the latter membrane, the orbital contents behind the eyeball were exposed, the finger inserted, and a very large mass, rounded, well-defined and somewhat firm, although elastic, was found to occupy the whole of the retro-bulbar region. This was, as far as possible, separated from the orbital bone wall, but it was found impossible to deliver such a large mass through the somewhat limited opening, and besides Mr. Thompson could not free it from its deeper and further attachments to the apex of the orbit and its immediate neighbourhood. Under the circumstances, as the eye was already useless, an excentration of the whole of the contents of the orbit was carried out by the usual method. There was profuse bleeding, but this was readily controlled by firm plugging. The wedge of bone taken from the outer wall, which had been wedged out of the orbit at the early part of the operation, was replaced *in situ*. The skin wound was sewn up. The plugs, of stoutest gauze, used to arrest the hæmorrhage were left, and firm bandaging was applied. Mr. Thompson said that he thought Kronlein's operation was quite justifiable in such a case, as it gave him a chance of enucleating the tumour and retaining the eye; this, although the eye was blind, would have been a great advantage to the patient. Unfortunately, the tumour proved to be too large for enucleation. In his opinion, Kronlein's operation was an admirable one for the removal from the orbit of all non-malignant growths and cysts, excluding, of course, vascular tumours and meningoceles extending into the orbit; but he did not consider it of any avail in cases of malignant growths when these could be diagnosed beforehand. He pointed out that malignant growth might be suspected when the mobility of the eye was early affected, and, of course, when the tumour was of rapid growth. In chiselling through the bone wall of the orbit, he said that the surgeon should use a narrow thin chisel, one edge being angled off and blunted so as to prevent injury to the soft tissues in the zygomatic fossa; the chiselling, too, should be done very slowly and gently so as to avoid splintering the orbital wall. The tumour should be separated as far as possible with the finger, and where the tumour grows around the optic nerve, the nerve must be divided with curved scissors first between the eyeball and the tumour, and finally between the tumour and the apex of the orbit. The best plan is to divide the external rectus between two sutures at the beginning of the operation so that the two portions of the muscle may be picked up and brought together by stitches at the end of the operation.

Six days after the operation the patient was doing well. The orbit is being washed out daily with peroxide of hydrogen.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

The President, Dr. E. H. Tweedy, F.R.C.P.I., in the Chair.

Meeting held Friday, April 10th, 1908.

A UTERINE TRACTOR.

Dr. Ashe exhibited a working model of an instrument which was, he said, intended to combine a sound with a tractor when necessary.

Dr. Neil spoke in commendation of the tractor.

PATHOLOGICAL REPORT ON ABNORMAL PLACENTA.

Dr. Spencer Sheill read the following pathological report by Dr. Rowlette on the abnormal placenta exhibited at the previous meeting of the Section, as some of the Fellows then present had stated that they had never seen a specimen similar to that exhibited by Dr. Sheill:—

"The placenta is slightly larger than normal, and quite firm. The umbilical vessels are very congested, and stand out prominently on the surface of the placenta. Completely surrounding the attachment of the cord, and at a distance of about two inches, is a raised ridge, varying from 1½ to 2½ ins. high; it bends towards the cord so as to form a deep fossa, the inner surface of the ridge being in apposition with the surface of the placenta. The membranes are closely adherent to the surface of the placenta, passing into the depth of the fossa and then over the ridge.

"Microscopically, the placental tissue is normal. At the ridge, however, the membrane is lifted from the tissue by a great mass of fibrinous coagulum, which is quite firm. The greater part of the ridge seems to be composed of fibrin. The condition must, therefore, be due to a sub-membranous hæmorrhage, for which I am unable to suggest any cause."

Sir A. V. Macan expressed the opinion that it was simply an exaggerated placenta circumvallata.

Dr. Sheill, in reply, said that although he was unable to suggest a probable cause for this placental abnormality, yet he could not agree with Sir Arthur Macan's opinion, inasmuch as he understood that the so-called placenta circumvallata invariably showed the chorion forming a rigid annular fold at the inner limit of the margin. Neither did he think it was a case of placenta marginata, for in these the chorion usually leaves the placenta before reaching its margin, thereby leaving a border free of membrane. In reply to a question of Sir Arthur's, Dr. Sheill said that in his specimen the chorion was attached all round to the placental margin in the usual way.

SMALL OVARIAN CYST, WITH COMPLETE DISAPPEARANCE OF OVARY.

Dr. R. D. Purefoy exhibited two pieces of the remains of a small cyst removed from a young unmarried patient. The particular point of interest in the specimen was that, notwithstanding the small size of the cyst, the ovary had disappeared, leaving nothing except a slight patch of thickening in one part.

A MYOMATOUS UTERUS.

Sir W. Smyly said his interest in the myomatous uterus—which he exhibited—was altogether technical. When he examined the patient he was unable to reach the cervix, owing to the extra-peritoneal development of the tumour on the right side of the uterus. When he operated he took the end of the tumour to be the cervix, and there was a depression in it which he took to be the os uteri. When he cut into the capsule there came a good deal of hæmorrhage, which astonished him. When he got it open enough to see where he was, he found he was in the capsule of the tumour, and had not opened the vagina at all. He then completed the operation—Doyen's method—in the usual way. The form of the tumour was exactly in the long axis of the uterus, and there was little wonder that he mistook it for the cervix.

Sir A. V. Macan said he was present at the operation, and could corroborate the difficulty of locating the cervix.

Professor Alfred Smith entirely approved of Sir W. Smyly's procedure.

Sir W. Smyly, in reply to a question by Dr. Jellett, said it was constantly stated that Doyen's operation shortened the vagina, but he himself had never seen any change in the vagina after the operation.

ADJOURNED DISCUSSION ON SIR A. MACAN'S PAPER ON THE OPERATIVE TREATMENT OF PUERPERAL INFECTION.

Dr. A. Holmes said it was very hard to make up one's mind, with a case not undoubtedly septic, as to whether an operation was justifiable or not. He had seen cases apparently at the point of death get perfectly well. Evacuation was of course, the best means of dealing with localised pus; and the opening through the posterior fornix—an easy operation which did not necessitate the removal of the patient from bed—had been followed by good results. When one considered the number of septic cases that existed, the mortality was really very small, and the number of cases of sepsis that recovered was very large, and he considered that it would be unwise to operate in all cases until differential diagnosis was more perfect.

Professor Alfred Smith said he knew of no uterine affection in which they seemed to be more at sea than in the treatment of puerperal fever; and while the Section was deeply indebted to Sir A. Macan for his thought-stimulating paper, he did not think that it showed any particular advance on the part of surgery in that line. They accepted generally the two great classes of infection—pyogenic and saprophytic; and they divided the former into the forms in which the infection was carried—(*a*) by the lymph ducts, and (*b*) by the blood stream. Bumm had demonstrated the fact that if a patient was infected by streptococcus, it developed and spread with such rapidity that there was no time for the surgeon to intervene. They were all in agreement as to the necessity of draining in cases of pus formation, though there was a difference of opinion as to the way in which they should reach the abscess. Sir A. Macan had proposed a special operation with a view to preventing the occurrence of general peritonitis; but he could not see the advantage of packing the entire pelvic cavity, seeing that the uterus, in a septic woman, after confinement, was almost up to the umbilicus, and that on the posterior wall of the uterus there was the great lymphatic plexus carrying large numbers of streptococci. On the Continent and in America cases had been successfully treated by ligation of the inflamed veins, but the whole difficulty one had to contend with was seeing when one should interfere at all by operation. He believed that the success of surgical procedures would be found in an early recognition of grave cases, and early operation. When they had more knowledge as to the type of bacillus that was causing the trouble, they might be able to do something to stem the fatal cases, and they might be able to devise methods to get a backward flow in the lymph-ducts, so as to prevent the invasion of the system.

Dr. Purefoy said he refused to believe that any examination of the contents of the uterus would enable them to make up their minds in every case, or even in any considerable number of cases, on the point of operative interference. In the cases of streptococcus infection, the spread of the disease was so rapid, and its diffusion through the system so general, that surgical measures did not hold out hope of saving life. They were unwilling to resort to early operation in these cases, because they were aware that apparently hopeless cases had recovered, and they were unable to determine the power of resistance in the patient.

Dr. Ashe spoke.

Dr. FitzGibbon said the great difficulty in treating by non-operative methods depended on diagnosing whether the condition was still localised or general, and anticipating general infection. If the infection had become general, it then became a question of whether the patient could fight the infection by natural resistance, and the only possible treatment they could adopt was the introduction of anti-toxins or vaccines to assist the system.

Dr. JELLETT said the more he thought about the subject the more hopelessly he seemed to be at sea. He could not understand where the operative treatment of acute puerperal fever came in. The operative treatment of local infections had been recognised for some time, but this was not what they were concerned with. Even if the presence of streptococci in the uterus was shown, the bacteriologist could give them no help as to the virulence of the organism until after injection into animals, and by that time either the patient was better or it was too late for operation. If the infection had not extended into the peritoneal cavity, it was contrary to all our present ideas to open up the cavity. If the infection had gone beyond the uterus, the analogy of limb-infection was fallacious, because the uterus was so intimately bound up with its connective tissue and lymphatics that the removal of the infection by removing the uterus seemed hopeless. If a patient got into a chronic condition of pyæmia, he could imagine that by removing the source of the infection in the uterus they might do a certain amount of good, as the extension of infection during the operation might be successfully overcome by the resistance set up by a long period of vaccination, so to speak. But in the early stage it did not seem possible to remove the uterus, with its load of infection, and open up the peritoneal cavity, without giving the patient such a dose of the organism as would do away with any good got by removing the prime source of the infection. Pryor, in America, had said, nine or ten years ago, that when there was a case of infection of the uterus that did not respond immediately to douching, they should open up Douglas' pouch straight away, and break down any adhesions and plug the pouch. His results were very good; but he (Dr. Jellett) could not help thinking that Dr. Pryor operated on many cases that would have got well without operation.

Dr. HORNE said it was comparatively seldom that one now saw a case of acute septic infection. The paper stated that the fifth rigor was an indication for operation, but in some of the very worst cases there was possibly only one rigor at the beginning, and to wait for the fifth would be to wait until too late. The plugging of the uterus and the opening of the posterior cul-de-sac was an admirable treatment, which he had adopted with very good results.

Dr. O'FARRELL said that Professor Sondern, (*a*) a New York pathologist, claimed that by means of a general and differential leucocyte count he was able not alone to ascertain the presence of a septic infection, but also to estimate the body resistance. Relative increase in polymorphonuclears indicates the presence of sepsis and the degree of leucocytosis the condition of the body resistance. It is not claimed that this is universally accurate, but Dr. Sondern considers it so important that he has an assistant on duty in his laboratory day and night, so as to be able to examine any patient's blood, and let the surgeon know without delay whether the blood conditions are such as to make operation desirable.

Sir W. SMYLY said it was very unlikely that any one of them would meet with more than a very few cases in which operative interference was required, and as it had been laid down that they could not judge the value of any particular line of treatment upon less than a hundred cases, it would probably take some centuries before any one institution would yield a sufficient number of cases. They had, therefore, to collect results from a great number of hospitals, and Sir A. Macan's paper was a valuable epitome of such results. He (Sir W. Smyly) objected to the title puerperal fever. In the old days it was restricted to acute lymphatic sepsis. Dr. Churchill had stated long ago that he had only seen seven cases of puerperal fever, and it was evident that the great majority of cases spoken of by Sir A. Macan were localised, not general, sepsis. In douching the uterus they were liable to do harm by opening up channels for the absorption of septic materials. One of the first things they had to do in a case of acute fever following child-birth was to try and clear the uterus with the finger, and he did not think there was any difficulty in doing so if they gave the patient an anæsthetic. He was not inclined to give up the flushing spoon-curette, and he thought the introduction of the brush would be more dangerous than the spoon. In treating puerperal fever, they should be careful not to take the part of the micro-organisms against the organism of the woman. The contest going on in her system was one of such great complexity that one felt very diffident to interfere; and it was very doubtful that a serum would not take the part of the bacteria against the tissues.

The PRESIDENT said his experience was that puerperal infection was common. Fortunately, in the majority of cases, it was of a mild type, and there was, in his experience, no complaint so amenable to surgical treatment. He divided it into the mild, acute and chronic types. The mild type was eminently suited for surgical interference. The chronic type was that dealt with for the most part by Sir A. Macan, and the acute type was outside the pale of all treatment. He divided operative treatment into the mild, the intermediate, and the drastic. Under the mild he put raising the bed, douches, exploration of the uterus, draining pus pools in the uterus, replacing a retroflexed uterus, the removal of pieces of placenta and membrane by the fingers. These could be undertaken without chloroform in the patient's own bed, and were highly successful. The intermediate (Pryor's) operation could be done in the patient's own bed, but required an anæsthetic; it could be conducted without fear of injuring the patient, and it was largely diagnostic as well as curative. The evacuation of pelvic pus through the vagina did not seem to give rise to septic infection. The more septic matter they got out of the system the better chance the leucocytes had to fight the remaining infection, and the opening through the posterior fornix nearly always let free a pool of turbulent peritonitic fluid in Douglas' cul-de-sac. If they could get a pelvic peritonitis well established the patient would probably worry through, and no procedure was more adapted to that purpose than plugging the whole pelvic cavity with iodoform gauze. He believed it impeded the circulation in the lymphatics. The anæsthetic was unfortunately very harmful when given to a septic patient. Until their knowledge was more precise, and their method of operation less calculated to bring about the dreaded shock, he did not think he would ever again open the abdomen above the pubes with the idea of tying off veins or removing a septic uterus. Anti-streptococcus serum was worthless when the disease had developed, though valuable as a prophylactic remedy. Where pus had burst into the abdomen, he gave the serum straight off. Vaccines were not applicable for such cases. Lactate of calcium would probably lock up the blood in the veins almost as well as by ligature.

Sir A. V. MACAN, in reply, said it might require a hundred cases to make statistics, but it did not require that number to enable them to have ideas on the subject. He had himself expressed his objection to the term puerperal fever, but there was no other term that embraced all the states including sepsis. The uterus had been recognised for a long time as the source of infection, and theoretically they must recognise a point at which—if they could settle it—the removal of the septic centre would be sufficient to stop the spread of the disease. The earlier they operated, the more successful they would be, but the more doubtful it would be as to the success of the operation. There was no finality in the operation; they were only at the beginning of it, and he believed there was a great future before it.

(*a*) Value of the Blood Counts in Sepsis." By Frederic E. Sondern, M.D., *New York Medical Journal,* June 16th, 1906.

THE portrait of Dr. Clement Dukes is to be presented to the Rugby Hospital, the President of the hospital having commissioned Mr. Harrison Dutton to paint it.

FRANCE.

Paris, May 3rd, 1908.

DRINK DIET IN CARDIO-RENAL AFFECTIONS.

DR. HUCHARD, in a recent communication before the meeting of the Académie de Médecine, recommended the cure of reduction of liquids in case of acute dilatation of the heart, accompanied with œdema. In such cases the usual cardiac and renal therapeutic agents fail miserably and place the life of the patient in jeopardy. The dilated heart has arrived at a period when resistance is no longer possible, while the congested kidneys invaded by interstitial œdema cannot support without danger the supplement of work imposed on them by diuretics. The rational therapeutic indication would be, on the contrary, to relieve these organs and thus facilitate their work.

For this reason Dr. Huchard allows only one pint of milk, and two pints of water, mineral or natural a day, and prescribes at the same time small doses of digitaline (1-10 milligs.).

Sol. of digitaline, 1-1000—50 drops.
Water, 5 ounces.

One tablespoonful a day, and theobromin (10 grs.) twice a day. After the third day of this treatment, abundant diuresis sets in, relieving the patient of the œdema.

Where the polyuria fails to be produced, the prognosis is fatal, as the dilatation of the heart is proved to be incurable.

Dr. Louis improves on this treatment by suppressing all liquid for a day or two, save a few tablespoonfuls of pure water to ease the thirst. By this simple means, the quantity of urine, which had not, perhaps, exceeded twenty ounces in the twenty-four hours, rapidly runs up to two and three quarts, secretion remaining abundant until all œdema has disappeared to the great astonishment of the patient, and those about him, who think the more a patient drinks the more he will urinate. When the œdema has disappeared, Dr. Louis administers digitaline, and theobromin in the doses recommended by Prof. Huchard, as excellent adjuvants in the subsequent treatment.

INTESTINAL ANTISEPSY IN CHILDREN.

Benzo-naphthol,
Lactose,
Salicylate of bismuth, } āā 10 grains.
Bicarbonate of soda,

Divide into five powders; one every two hours. (For child of six months.)

Benzonaphthol,
Salicylate of bismuth, } 2 grains.
Resorcine, 1 grain.

For one powder. No. 6. One every two hours. (1-2 years).

Salol, 2 grains.
Subnitrate of bismuth, 20 grains.
Bicarbonate of soda, 20 grains.
Syrup of gum, 4 drachms.
Water, 3 ounces.

A teaspoonful every two hours.

Lactic acid, ½ drachm.
Syrup of orange, 1 ounce.
Water, 3 ounces.

A teaspoonful every hour.

Oxygen water (12 vol.), 3 ounces.
Chloride of sodium, 1 drachm.
Phosphate of soda, ½ drachm.
Bicarbonate of soda, 10 grains.
Boiled water, 1 quart.

The whole to be given as an enema, and renewed twice a day in cases of enteritis of divers origin.

ORCHITIS.

Guaiacol, 4 drachms.
Lard, 2 ounces.

Rub gently over the inflamed organ. Apply cotton-wool, and a suspensory bandage. At the end of week of this treatment, prescribe:—

Mercurial ointment,
Belladonna ointment,
Ichthyol, } 1 drachm.
Lanoline,

MEDULLARY ANÆSTHESIA.

Regional anæsthesia by the introduction of a solution of stovaine or cocaine into the rachis in the lumbar region is no longer in favour on account of the divers accidents occasioned by this treatment. At the last meeting of the Surgical Society, M. Legueu related that he had hitherto been a great partisan of this kind of anæsthesia, having practised it over 300 times, but was now inclined to renounce it on account of the troublesome after effects he observed in many of the cases: malaise, feeling of anguish, fainting, cephalalgia, retention of urine, this latter lasting six months in one individual.

A patient operated on for hernia was seized with headache, vomiting, and paralysis; he died at the end of six weeks. Another presented the same symptoms, with retention of urine.

Several other members confirmed the danger of this method, which would only find its indication when chloroform could not be administered with safety.

M. Reclus said he never practised this method; he preferred employing local anæsthesia, with cocaine or associated with stovaine. He never had an accident, although the dose of cocaine injected attained sometimes six grains.

GERMANY.

Berlin, May 3rd, 1908.

THE *Deutsche Medizinal Zeitung*, No. 12, contains an interesting abstract of a paper by Dr. W. Siegel, of Bad Reichenhall, on "Chills as Causes of Disease." He first of all points to the general view that at present prevails—viz., that the simultaneous occurrence of a chill and the presence of bacteria are sufficient for the production of disease. The hyperæmia of the internal organs, proved to be a result of contraction of the cutaneous vessels caused by chilling, is supposed to excite the germs into action, to make them virulent (Hofbauer), and to favour their settlement (Lode). According to F. Müller, it was possible that the slowed circulation of the blood at the part cooled acted injuriously in some way, and that in this way poisonous material might be formed. Probably, however, the cooling only caused a diminished power of resistance to injury. Reduction of temperature could not favour the development of bacteria in any way, as the optimum of temperature of organisms injurious to the human subject was exactly that of the body.

Some authors considered an antecedent over-heating of the body to be unconditionally necessary to chilling. The statement in the general conception was not correct. Even if many colds arose in this way, we knew that in the spring time of the year, the time of melted snows, damp weather, warm, moist spring winds, numbers of people took cold without any previous over-heating. The moistness of the ground and of the air, with a low temperature, played an important part. Gentle and moderate breezes were of importance, whilst strong winds, with dry air and dry cold, were almost free from danger, and only led to colds—*i.e.*, of the nose, the ears, or chilblains. Wetting of the body, whether total or partial, was also of importance.

But, in spite of germs and the chance of taking cold, one was far from coming on in all cases. There must be another factor, therefore, and that lay in the individual himself. For the cold to come on there must be an individual disposition, and in some people this disposition was permanent, in others only transient and momentary, so that in the latter class of people the cold came on when the disposition at the moment favoured its onset; there was no such thing as absolute immunity.

The speaker then described his experiments on the cooling of dogs made in the Second Medical Klinik with a view of setting up acute nephritis. This disease had been thrust aside by the predominance of the views as to bacteria, and was not even looked at. The speaker had cooled dogs by applying ice to a surface of the back 4 to 5 cm. in diameter; other dogs he had made to stand with their hind-quarters in water of a temperature of 40° C. In all cases the clinical symptoms of acute parenchymatous nephritis came on, the diagnosis being confirmed by post-mortem examination. This proved experimentally the possibility of acute nephritis being set up by cooling and wetting. He had also observed that in time of snowfall and damp weather, nearly all the dogs brought to the laboratory showed traces of kidney irritation—a further support for his theory of chill.

In explaining the mechanism of the process, the speaker relied on the experiments of Wertheimer, who observed a vaso-constrictor action in the kidneys as a result of the application of cold. This anæmia, the opposite of the hyperæmia that took place in the lungs under similar conditions, in Siegel's opinion led to a disturbance of nutrition, which let loose the inflammatory process.

At the Silesian Society, Professor Küttner (Breslau), amongst a number of other cases, showed one of

Intermittent Hydronephrosis with Abnormally-placed Supernumerary Renal Artery.

The case was that of a man, æt. 28, who every three weeks for six years had had attacks of abdominal pain. It was at first attributed to the stomach, then to gall-stones; he had also been treated for rheumatism and other things. From the pain starting from the right testicle, attention was drawn to the right kidney, but chromocystoscopy showed that the kidney was acting. The absence of concretions as shown by the X-rays and negative palpation of the kidney region, together with exclusion of floating kidney, led to a diagnosis of "intermitting hydronephrosis in an ectopic kidney caused by congenital anomaly." At the operation it was found that the ureter was crossed transversely and kinked by a supernumerary artery. As a plastic operation seemed uncertain in its results and dangerous, and as the other kidney was healthy, the kidney was removed.

AUSTRIA.

Vienna, May 3rd, 1908.

Rhinogenic Retrobulbar Neuritis Optica.

Rethi presented a case he had operated on for retrobulbar neuritis by the intra-nasal operation on the ethmoid bone. It often happens that this thin sheath, no thicker than paper, that divides the optic from the cellular portion of the bone, becomes involved in the inflammatory process, which is in turn transmitted from the nasal cavity. The patient had been suddenly affected with blindness after a nasal catarrh, and, finding no relief, decided to submit to the operation, with excellent results. The vision is now fairly good.

Intra-Uterine Pessaries.

Natanson reported a case of a woman who had worn an internal pessary for five weeks with disastrous results. She now suffers from an obstinate catarrh of the cervix, which has impaired the strength and reduced the constitution. These foolish "Frauenschutz" ought to be condemned as a dangerous interference with the person.

Spasms and Dilatation of Œsophagus.

Zueig showed a patient who had suffered from severe spasms of the cardiac end of the œsophagus, with consequent dilatation of the œsophagus higher up. Zueig succeeded in relieving this spasm by means of a sound or catheter armed with a "condom," which he filled with air by means of an air-ball, and distended the contracted portion of the canal.

Lotheissen thought that Kausch's bougie was well adapted for this operation, where the "condom" could be filled with water for the dilatation of the stricture. In any case the prognosis of such cases is never very hopeful.

Orthostatic Albuminuria.

Steiskal next read a paper on the subject, and said 77 per cent. of these cases occurred among the young, and exhibited the following symptoms: weariness, headache, vertigo, fainting, rushing in the ears, palpitation, pain in the back, and was frequently associated with dyspnœa and constipation. The skin is usually pale, and the muscles flaccid, increased cardiac dulness and systolic murmur. There is also present accentuation of the second pulmonary sound, though more seldom the secondary aortic sound. After standing upright for a short time, the urine is found to contain albumin that is deposited by acetic acid, but no other nephritic sediment can be found in the urine. This orthostatic albuminuria usually persists from two to seventeen years, and is more frequent among young persons than is commonly believed.

As to the real ætiology of the disease, no unanimity can be arrived at. Some authors attribute this morbid condition to a suppressed or antecedent nephritis; others consider it a congenital anatomical abnormality, as Leube; another section of writers consider it constitutional enfeeblement or an insufficient innervation of the heart and blood-vessels. More recently Jehle has attributed this change to a mechanical cause in a deformity of the spine, such as an increased lordosis in the lumbar vertebræ, which, he contends, presses on the kidney in youth when the body is brought into the orthostatic condition, and thus produces pathogenic albuminuria. Whatever truth there may be in this latest hypothesis, Steiskal thinks that many facts are in favour of the theory. Within his own observation he has had recently five cases of severe lordosis which were confined to bed, but placing them in the erect posture for a quarter to a half-hour, and examining the urine immediately after, it was found to contain this peculiar albumin deposited by acetic acid. In others he has been unable to obtain the same results, and from the small number of positive cases he is disinclined to accept Jehle's theory, and believes that nephritis, puberty, or nervous disturbance is more likely to be the determining factor.

HUNGARY.

Budapest, May 3rd, 1908.

At the recent meeting of the Interhospital Medical Association, Prof. Preisich read a paper on

The Agglutination of Tubercle Bacilli in Animals.

According to him, the blood serum of healthy rabbits never agglutinates tubercle bacilli, but if rabbits are experimentally infected, as has been done first by Dr. Schvarzkorf, the test is positive in only one-half of the animals. The agglutination is most frequent about three weeks after infection, and gradually decreases as the tubercles surround themselves with connective tissue. This corresponds with the clinical experience that the phenomenon is more common with tuberculous patients in the first stage than with those in the third. Animals near death also failed to react. Animals infected with strongly virulent bacilli of bovine tuberculosis agglutinated less frequent than where less virulent germs of human origin were employed. Positive results were occasionally obtained where no pathological lesions were found. It seems very improbable from these experiments that the test will ever be of much diagnostic value in man.

On the Urine Ferments.

Dr. Kiss said that every urine contains proteolytic ferment. This is generally pepsin; while during the absorption of pathological infiltrates and exudates, and in diabetes mellitus, trypsin is occasionally found (Arany). By determining the critical temperature, the author could prove the gastric and urinary pepsin are identical bodies; furthermore, if the stomach in animals is extirpated, no more pepsin will be excreted. During fasting the amount is considerably higher than normally. It is probable that the excess of ferment is absorbed by the blood as zymogen, and is again converted into pepsin, where it encounters an acid reaction, as in the kidneys.

Cystoscopy of Exudates.

Prof. Kétly and Torday have, in a series of articles in the *Orvosi Hetilap*, dealt with the question of the value of cystoscopy in determining whether a collection of fluid will be absorbed spontaneously or not. Thus, in chronic pleural exudates, absorption can be looked for where the lowering of the freezing point is close to or less than that of the blood serum. This, however, applies only to those cases where there is no fever or other sign of pleural inflammation, since here an increase of effusion can be expected. In cases of hydrothorax secondary to nephritis, the freezing point of the serum must also be determined, and the figures are only of value if renal function is satisfactory. The rules for pleural fluids also hold for those depending on tuberculous peritonitis. In other peritoneal transudates, cystoscopic examination is in place only where there is no mechanical obstruction, and the heart's action must always be taken into account before giving a decision. It is often hard to distinguish between exudates and transudates, since the specific gravity and amount of albumin may vary within wide limits in both. The authors had hoped that cystoscopy might be of some help, but numerous experiments conducted in this direction were without result.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE RUCHILL HOSPITAL AFFAIR.—Last Thursday, the Glasgow Town Council met and had a very protracted and heated debate over Ruchill Hospital, and the medical officers responsible for its administration. Those involved were Dr. Chalmers, the Medical Officer of Health for Glasgow, Dr. Johnston, Physician Superintendent of Ruchill Hospital, the matron, and the assistant medical officers, who, having failed to get their grievances redressed, appealed to the Local Government Board, which led to an official inquiry and report. The Local Government Board found the grievances of the dismissed assistant medical officers were fully substantiated, and subsequently a subcommittee of the Health Committee specially investigated the matter and furnished two reports—a majority report and a minority report, to the Town Council, now discussed. The majority report exonerated Dr. Chalmers from any blame in regard to the administration of Ruchill Hospital, during the time its wards were overcrowded and its staff inadequate for the extra work created by the epidemics of measles and cerebro-spinal meningitis. The minority report, however, stated "that the facts that the medical officer of health regularly received from the physician superintendent daily returns of the number of patients in each ward and that the physician superintendent was placed under his control as well as the control of the sub-committee, imposed upon the medical officer of health the duty of carefully examining these daily returns and calling the attention of the sub-committee to the excessive overcrowding of particular wards." In regard to the physician superintendent, the majority report stated that "It is with the greatest possible regret that the sub-committee feel themselves obliged to recommend that the physician superintendent be asked to tender his resignation." They further stated that they were of opinion that "the physician superintendent lacked the administrative capacity necessary to the successful management of a great hospital." The minority report considered that to dismiss Dr. Johnston would be too great a punishment, and that in view of the exceptional circumstances of the case and his previous 15 years of approved service, that he be put on probation for six months. The vote in the Town Council was as follows:—(1) For the majority report, that Dr. Chalmers be exonerated from blame, there were 36 votes in favour, 30 votes against. (2) For the minority report, that Dr. Johnston's services be retained, there were 34 votes in favour, 31 votes against. (3) It was resolved to retain the services of the matron. (4) That the dismissed assistants be not reinstated, there were 36 votes in favour, 15 against. The practical upshot is that there is a return to the *status quo*, except that the dismissed assistants are not to be reinstated, which seems not only a lame and impotent conclusion, but one lacking in the elements of justice and good management.

FUNERAL OF THE LATE DR. C. E. UNDERHILL, OF EDINBURGH.—As a last token of respect to their late President, the Fellows of the College of Physicians attended the funeral ceremony, which took place in St. John's Church, Edinburgh, on April 27th. The Fellows of the College of Surgeons were also present, as well as a large gathering of the public, including representatives of the Edinburgh Corporation. The service was conducted by the Bishop of Edinburgh and Canon Cowley Brown.

GLASGOW MATERNITY HOSPITAL.—The new buildings of the Glasgow Maternity Hospital, recently erected in Rotten Row at a cost of £80,000, were opened on April 30th by the Duchess of Montrose. Among those present were Principal McAlister, Sir Halliday Croom, and Professor Murdoch Cameron. Sir J. Halliday Croom conveyed from his colleagues in Edinburgh their heartiest congratulations. He had gone over the hospital and found it second to none in the United Kingdom—indeed, he might say it was unequalled anywhere.

BELFAST.

BELFAST OPHTHALMIC HOSPITAL.—At the annual meeting of this hospital, held a few days since, the medical staff report was read by Dr. Cecil Shaw, and showed an increasing amount of work done in the hospital. The eye patients seen in the extern department during the last year numbered 1,372, and the throat and ear patients 703. In the wards 173 patients were treated, and 135 operations performed, besides numerous minor operations in the extern. An urgent appeal was made by the staff for funds to enlarge and remodel the extern department, and bring it up to date, for which purpose about £500 would be required. Dr. Walton Browne urged the necessity for this expenditure, and the Bishop of Down begged eloquently for the help the medical staff asked for. Several donations of from £5 to £25 were promised at the end of the meeting.

LETTERS TO THE EDITOR.

THE BRITISH MEDICAL ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my letter published on March 25th I spoke of the enormous cost of the *British Medical Journal*, and suggested that the Association was falling into the position of a mere co-operative society for the publication of a cheap medical newspaper. In the Supplement to the *Journal* to-day are published the official accounts. From these it appears that the *Journal* is costing the Association over £30,000 a year. Of this vast sum more than £5,000 is spent on editorial salaries and editorial contributions. The *Journal* is three times too bulky in every department. If the members will not unite to make their voices heard, to assert themselves, and demand the minimum of political power which is their just due, no journal, however big and however well written, is of much use. On the other hand, if the profession could be roused to combined action, it would not matter how small the organ reporting their proceedings might be. If the Association is only kept together as a band of subscribers to a cheap paper, the sooner the connection is destroyed the better; at least, so it seems to me. The paper is cheap to members, but its production involves the waste of a vast sum annually.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

May 1st, 1908.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As a member and well-wisher of the British Medical Association, I would suggest that the money so generously subscribed to its funds by the profession should in a large measure be devoted to the interests of its less fortunate members, who, through illness or other adverse causes, are themselves in distress, or, through death, have left widows and children in dire need of help; instead of, as now, in the production of a huge *Journal* (which it is impossible for busy men to wade through week after week), and in building palatial offices in London which the Association can do perfectly well without. When I think of the enormous sums spent on these two items, and what could be done with, say, half the amount if judiciously administered as a "Relief Fund," I marvel that a Council of medical men should be swayed in their acts by such grandiose measures rather than by motives of common humanity.

I am, Sir, yours truly,
Harley Street.

London, May 3rd, 1908.

OBITUARY.

DR. WILLIAM AICKIN, OF BELFAST.

Last week another of the seniors of the medical profession in the Belfast district passed away. Dr. William Aickin graduated in the Queen's University in 1855, and practised as a family physician in Belfast till his retirement some five years ago. He was a singularly shy and retiring man, and took no active part in public or professional affairs, but he was universally respected as a capable physician, a kind friend, and an upright citizen. Outside his professional work, his chief interest lay in the affairs of the Methodist Church, of which he was a devoted member, and to whose funds he was a generous contributor.

DR. J. C. DALY.

Medical men, particularly those who are interested in athletics and who remember events of 20 years ago, will learn with much regret of the death of Dr. James Carroll Daly, J.P., of Borrisokane, which occurred last week in Dublin as a result of blood-poisoning. Dr. Daly's fame in the athletic world was won by him in early life. He was of powerful build—6ft. 2½in. in height; weight, 26st. For years he held the world's championship record for throwing heavy weights, and his record in pushing the 56 lb. off the shoulder holds good still. He was one of the Irish representatives in what was known as "the Gaelic Invasion of the U.S." in the eighties, and though he had never gone in for a regular course of athletic training, he astonished the athletic world by his great strength and agility. He was dispensary doctor for Borrisokane for more than twenty years, and J.P. of Tipperary County for the past ten years, being as popular as he was famous. The people of Borrisokane, among whom he lived for the past twenty years, will mourn his loss.

DEPUTY SURGEON-GENERAL W. S. OLIVER.

The death is reported of Deputy Surg.-Gen. William Silver Oliver, M.D., late Army Medical Department, at the age of 72. He entered the Army Medical Service in 1857, was promoted Surgeon in 1872, Surgeon-Major in 1873, and Brigade-Surgeon in 1882, retiring with the honorary rank of Deputy Surgeon-General in May, 1883. He served in the campaign in Rohilkund in 1858, including the actions of Bugawalla and Nugena, relief of Moradabad, action on the Dojura, assault and capture of Bareilly, attack and bombardment of Shahjehanpore, and various other Indian battles. He also took part in the Oude Campaign, including the actions of Pusgaon, Rissoolpore, Mehundee and Biswah, receiving the medal for distinguished bravery. His last campaign was in 1870, with the 60th Rifles in the Red River Expedition.

The Home Secretary has appointed a departmental committee to inquire into the operation of the law relating to inebriates and to their detention in reformatories and retreats. Among the members are the following medical men:—R. W. Branthwaite, Esq., M.D., H.M. Inspector of Inebriate Reformatories; H. E. Bruce-Porter, Esq., M.D.; H. B. Donkin, Esq., M.D., one of H.M. Commissioners of Prisons; C. A. Mercier, Esq., M.D., Physician for Mental Diseases to Charing Cross Hospital.

SPECIAL ARTICLES.

THE HEALTH OF THE ARMY.

The Report on "The Health of the Army for the Year 1906" (*a*) is arranged in somewhat a different form from that to which we have been accustomed. Formerly, the letterpress consisted chiefly of comments on the various tables and abstracts. In the present volume, while the statistical information is arranged much as heretofore, the letterpress is more independent of it, and is arranged so as to give a general history of the health of the Army, in its different stations, for ten years, mention being made only of the chief causes of disease, and of the general lines on which the problem of prevention has been approached. The result is that we are furnished with a more readable narrative than formerly; but, on the other hand, it is somewhat more difficult to obtain specific information on any desired point. Uniformity of arrangement is of great convenience in a series of public reports, and we are not sure that the advantages of the re-arrangement in this instance outweigh the disadvantages.

A distinct advance in the present volume, however, is the more extensive use made of curves and graphic methods of representing comparative figures. Also, where contrasts are made with the figures for previous years, the information goes back to 1890, and we are not furnished merely, as heretofore, with decimal averages. We are, therefore, able to see at a glance certain marked contrasts which previously were hidden in complicated tables. Taking the health of the Army as a whole, for the year 1906, and comparing it with that of previous years, there has been, on the whole, a distinct improvement. Thus, to begin with, the admissions to hospital have fallen steadily during the past 16 years from nearly 1,060 per 1,000 of strength, to less than 600. To a certain extent this has been due, no doubt, to the introduction of the system of treating a considerable number of the slighter cases of disease or injury as out-patients, but the fall commenced some years prior to the introduction of this system. In all probability the chief cause of this reduction in the number of admissions is largely due to a reduction in the admissions for venereal diseases. In the year 1890 the admissions from syphilis and gonorrhœa in the two most important divisions of the Army, namely, those stationed in the United Kingdom and in India, were 196 and 376 per 1,000; during the year 1906 they had fallen to 68 per 1,000 and 88 per 1,000 respectively.

Other diseases have also shared in the general reduction. Thus, in the group of general diseases (confining ourselves still to the troops serving at Home and in India, which are most continuously uniform in strength and composition of all the divisions of the Army), we find that there was a decrease in admissions of about 66 per cent. at Home and about 30 per cent. in India. Tubercle of the lung showed, in 1890, nearly 4 admissions per 1,000 of strength in the United Kingdom, and 3.26 per 1,000 in India. These figures had fallen in 1906 to less than 3 per 1,000 in the former case, and somewhat under 2 in the latter. Diseases of the nervous system accounted for 9.3 admissions per 1,000 in the Army serving at home in the year 1890, and for 10.3 in the Army of India in the same year. In 1906 this group of diseases showed an admission rate of only 6.25 and 9.88 in the two armies respectively. The admission rate for diseases of the circulatory system fell, in the 16 years under review, by nearly 75 per cent. at home and 25 per cent. in India. Diseases of the digestive system showed a decrease during the same period of 25 per cent. among the troops serving in the United Kingdom, and one of about 10 per cent. among those serving in India. The above facts show that the improvement in the general health of the Army, since 1890, cannot be attributed to a decrease in the incidence of one particular disease, but to a general improvement in all directions. It is probable that one great cause of this is the increase of temperance in the Army during late years, but the greater proportion of the improvement may fairly be attributed to improved sanitation, both as regards the housing and clothing of troops, and also as regards increased knowledge of how to combat disease, not only on the part of the Medical Department, but that of the Army in general.

It is of interest to compare the health of the British Army with that of foreign armies.

Taking all diseases we find that the United States Army heads the list with the enormous admission rate of 1,250 per 1,000. After this come the French, German, and Austrian Armies all above 600. Fifth in the list is the British Army, serving in the United Kingdom, and lowest of all, the Russian Army with the low figure of 324 admissions per 1,000. Too much stress must not, however, be laid on these figures when used for purposes of comparison. They are naturally to a great extent dependent on the regulations as to out-patient treatment and other service customs, which vary considerably in different armies. This comparison cannot be regarded as unsatisfactory from the British point of view, since there is no army which has to serve so much of its time on foreign stations as the British, and therefore none so exposed to disease.

Taking individual diseases or groups of diseases, we find that as regards enteric fever the French Army suffers by far the most of all the armies under discussion, its admission rate of 14.1 per 1,000 being not much below that of the British Army in India—viz., 15.6 per 1,000 for 1906. The Russian and United States Armies come next with 3.8 and 3.57 per 1,000, then the Austro-Hungarian and German Armies, while the British Army occupies the lowest place.

As regards venereal diseases, the American Army again comes first with the very high ratio of 178.72 per 1,000; the British Army second with 81.8. It is noteworthy, however, that in the case of the American Army the admission rate for these diseases has been steadily increasing for the last nine years, whereas in our Army it has been steadily falling for a considerable period. The French and Austro-Hungarian Armies come next, followed by the Russian Army at a slightly longer interval, while the German Army comes last with the very low ratio of 19.8.

The unsatisfactory condition of the British Army as regards these diseases rouses serious thought. It is useless to think of reviving the Contagious Diseases Acts, since—whether a wise step or not—public opinion is stubborn against such a measure. Nevertheless, we believe that by careful teaching of recruits, much might be done to protect them. Many of these lads are entirely ignorant of the dangers they run, and of the means by which they might to some extent protect themselves. Doubtless the improvement already noticed is due to an improved moral feeling, and there is hope for still further progress on the same lines. At the same time, it is folly to disregard the temptations to which "single men in barracks" are specially subjected, and to imagine that these temptations will always be conquered. In the German Army and Navy a careful teaching of and provision for personal hygiene has been one of the effective steps in reducing the incidence of venereal disease.

As regards tubercle of the lung, France and America head the list, England and Russia coming together with ratios less than one-half those of the two first-named nations. Germany and Austro-Hungary come last with ratios about one-half of the English and Russian Armies.

Cardiac affections are much more prevalent in the Army in the United Kingdom than in any other Army. America and Germany come next, France and Russia about level, and Austro-Hungary last of all. The high rate in the British Army is usually attributed to the poor condition of the recruit on enlistment, and the severity of the training through which he has, till lately, been put.

As regards the British Army, a comparison of returns from the various regions in which it serves is of interest. The admission rates per 1,000 are:—United Kingdom, 446.7; Mediterranean, 515.5; South Africa, 422.2; India, 871; on board ship, 761.3; all other stations, 693.8. The mortality rates vary from 2.92 per 1,000 at home to 10.81 in India.

One always turns to the sections on the examination for recruits for some information as to the condition of physique of the classes from which the Army chiefly replenishes itself. We find that the defect which caused the highest proportion of rejections was loss or decay of many teeth (59.63 per 1,000 of those inspected), and close to it came deficient chest measurement (49.48). Defective vision caused 28.46 rejections per 1,000, disease of heart 30.74, varix 11.75, varicocele 12.78, defects of lower extremities 21.37, under height, 10.85, under weight 11.27.

THE SOCIAL CONDITION OF DUBLIN WORKING-CLASS FAMILIES.

Mr. C. D. La Touche and Dr. T. J. Stafford publish, under the date May, 1907, a "Note on the Social Condition of Certain Working-Class Families in Dublin," which, however, seems only to have seen the light within the past few weeks. For our copy we are indebted to the courtesy of the Medical Commissioner of the Local Government Board for Ireland, but the note bears no information as to publisher or where it may be purchased. This is the more unfortunate, as the subject-matter is of much interest to all concerned in sociological inquiries.

The object of the inquiry was to determine how the typical Dublin labourer lives, what are the conditions under which he and his family are housed and fed, and what are their average family earnings. It was not intended to investigate the circumstances of the very poor. In the pursuit of the inquiry the authors have collected particulars of the earnings, spendings, housing, family, and diet of a large number of labourers.

The first table, which deals chiefly with housing questions, is based on an examination of 1,254 families, consisting of 4.950 persons, giving an average of 4.12 persons per family. They occupied 1,903 rooms. Barely 12 per cent. of these had accommodation satisfactory as regards sanitary convenience, air-space, and cleanliness. 87 per cent. suffered from unsatisfactory sanitation; 60 per cent. of the families were confined to single-room tenements. In the case of 5 per cent. the housing conditions were in all respects unsatisfactory.

The earnings varied from under 5s. to over 60s. a week, the average being 22s. 2d. per week per family, and the average rental was 3s. 0¾d. per family. As regards the incidence of consumption, the authors found that disease present in 12 per cent. of the families.

The second table is based on 21 families, and deals with the expenditure and earnings, or what the authors term the "family budget." The average number of persons per family was 4.57, and the average weekly earnings 23s. 2½d. Taking them as a whole, it was found that 98.35 per cent. of the total income was expended, while it would appear that in the case of ten out of the twenty-one the expenditure exceeded the income. Of the different items of expenditure, food absorbed 63.38 per cent. of income, and rent 14.51 per cent.

In the study of the diet, the authors have carefully calculated the protein value and the fuel-value of the different dietaries they found in use. Adopting Mr. Rowntree's arbitrary poverty-line, it was found that twelve out of the twenty-one families fell below that line.

The authors seem to have got no information as to expenditure on alcoholic liquors, but they find a considerable contribution to revenue under the heads of sugar and tea. In 1904 this contribution amounted to 2.99 per cent., and in 1907 to 2.31 per cent. of the family's weekly earnings.

The authors suggest a more satisfactory dietary, related to the tastes of the people, which would give a reasonable variety of food, and yield sufficient nutriment at the rate of 125 grammes of protein per man per day.

The Fourteenth Chemists' Exhibition was opened at the Royal Horticultural Hall, Vincent Square, Westminster, on Monday, May 4th. No doubt a great deal of interest will be taken in this Exhibition by medical men, who will find ready for inspection all the latest and best practical advances in the art of pharmacy.

REVIEWS OF BOOKS.

PREVENTABLE BLINDNESS. (*a*)

No more important subject could have been chosen by the author for a monograph than this, seeing that more than one-third of the blindness found amongst school children is due to ophthalmia neonatorum, and therefore preventable. In his historical introduction the writer refers to Biblical and other examples of persons "blind from birth." The causes of blindness form a subject for very careful study in the next chapter. Ophthalmia neonatorum, we find, heads the list, and represents a very high percentage (36.36) of cases of blindness. The incidence of this disease in London is very great. Out of every 100 children born, one suffers from purulent inflammation of the eyes in the first few days of life, and of every 2,000 children born, one child is blinded or partially blinded by this disease.

The clinical characters and the bacteriology of the disease are very fully treated in this volume. Most cases are undoubtedly due to invasion by the gonococcus, although other organisms are sometimes found in the stained film. A somewhat lengthy chapter on treatment is given, as well as one on the prevention of the disease. The writer suggests that ophthalmia neonatorum should be added to the list of notifiable diseases under the Act of 1889, in order to prevent, if possible, its spreading to others and to minimise its risks to the individual. With this suggestion we cordially agree, although there are difficulties in the way of carrying it out under the existing state of our municipal machinery.

This small book will repay careful perusal, and it certainly supplies a large amount of important information on a subject which, undoubtedly, is one of great national importance. The printing, binding, and general get-up of the volume call for a word of special praise.

NATURE'S HYGIENE. (*b*)

THIS well-known work has now reached a fifth edition. The volume is one of great interest, containing, as it does, an excellent account of matters affecting the public health, such as ventilation, drinking water, sewage disposal, germ diseases, and disinfection. Although it can hardly be termed a manual of hygiene in the strict sense, this volume, nevertheless, supplies the reader with a great deal of useful and practical information not readily found elsewhere. The author, for example, has brought together a number of interesting facts and figures in his chapter on sewage and sewage disposal. He incidentally refers to his proposed method of treating sewage by means of powdered coke, which has the property of absorbing ammonia, sulphuretted hydrogen, and other offensive gases. The sludge which results can be easily pressed and constitutes a fairly good manure.

The second part of the volume deals with the chemistry of essential oils and their oxidation products. Eucalyptus, pine, and camphor forests are also referred to, and their hygienic influences fully considered. In this edition several pages have been added concerning the more recently discovered chemical elements and other matters of present-day interest. Taken as a whole, this book affords much interesting material for the medical officer of health, who will find its pages full of suggestiveness. The author puts his facts before the reader in a clear and practical manner, so that the volume forms very good reading for those interested in matters pertaining to hygiene. In its present form this work is sure to find many readers, not only amongst the medical profession, but also amongst those who have to deal with municipal affairs.

LITERARY NOTES.

THE "Formulaire des Médicaments Nouveaux" for 1908 (J. B. Baillière et Fils, Paris), which is now in its twentieth edition, is a most serviceable compilation. The present volume contains a large number of additions, many of which are quite new to us. Among them are assuredly some that have come to stay, while others, it may be apprehended, are mere motes floating in the therapeutical sun. In the former category we should place arbeol, the active principle of sandalwood oil; atoxyl, the new arsenical compound of which so much is hoped; bromiase, a compound of bromide of potassium and levurine which, it is claimed, never gives rise to "bromism"; chloretone; vanadic acid and mercurial vasogene. Then, too, there are the colloids—sometimes called the electric colloids from their mode of preparation. These appear to be possessed of really remarkable therapeutical properties. The appendix, or "Dictionary of Synonyms," will often be found useful in the present transitional state of nomenclature. Altogether a very handy little compendium of current materia medica.

THE second edition of Dr. George Oliver's "Studies in Blood Pressure" (London, H. K. Lewis, 1908) bears evidence of further careful work on this interesting subject. It is largely due to the author's teaching that the clinical value of observations of the blood pressure is now more generally appreciated; indeed, as the apparatus becomes simplified, a hæmomanometer is likely to be found as indispensable as a thermometer. This process of simplification is going on, and the author figures his latest modification, the compressed air hæmomanometer, which, it is claimed, eliminates certain fallacies due to abnormal resistance on the part of the arterial walls. We are reminded that it is easy to misinterpret the significance and exaggerate the importance of variations of blood pressure, which, after all, is only one factor in determining the physiological conditions. Considered in its proper relationship to other indications, arterial tension, however, is one of unquestionable value, and, like the sphygmograph and the thermometer, will often confirm or suggest the existence of pathological states. We know of no more complete and straightforward guide than this well-thought-out little treatise on the subject.

THE Committee of the National Children's Home and Orphanage have issued, in pamphlet form, an account of their recent London Mansion House meeting. Their immediate object is to provide a sanatorium for children who are threatened with consumption. In making this attempt they are falling into line with the teaching of modern medical science, which regards prevention as the crucial aim, far exceeding in importance any merely curative organisations, however necessary and desirable the latter may be. Every medical man knows that in tuberculosis, above all other human maladies, to be early in the field is half the battle. The National Orphanage Committee, therefore, have, so to speak, hit the nail on the head when they are offering a good environment to children who are either predisposed to the disease or who are suffering from its early manifestations.

⁂

AT the Mansion House the Lord Mayor, Sir John Bell, presided, being supported by the Lady Mayoress and the Sheriffs. Among others present may be mentioned Alderman Sir Thomas Crosby, M.D., Sir John McDougall, and a number of distinguished persons, both lay and medical. Sir Douglas Powell made an eloquent appeal on behalf of the children. One of his most striking points was the demonstration that, while some 25 per cent. of the infantile population were born of consumptive parents, only 10 per cent. were definitely tubercular, and required sanatorium treatment. Sir Thomas Barlow followed with a full and exhaustive review of the position, and referred to the advisory position of Dr. Kelynack with regard to the Children's Home. Mr. Sheriff Wakefield, Sir Horace Marshall, and others also addressed the meeting. It appears the Committee have purchased some ten acres of land at Harpenden, Herts., for the further-

---

(*a*) "Preventable Blindness: An Account of the Disease known as the Ophthalmia of the New-Born and of its Effects: With a Plea for Its Suppression." By N. Bishop Harman, M.A., M.B. Cantab., F.R.C.S.Eng., Ophthalmic Surgeon to the Belgrave Hospital for Children, etc., etc. London: Bailliere, Tindall and Cox. 1908. Price 2s. 6d. net.

(*a*) "Nature's Hygiene and Sanitary Chemistry." By C. T. Kingzett, F.I.C., F.C.S., Past Vice-President of the Society of Public Analysts, etc. Demy 8vo. Pp. xvi., 527. 5th Edition. London: Bailliere, Tindall and Cox. 1908.

ance of their excellent scheme. This effort is well worthy the help of philanthropists. It forms part of the greater movement which for some years past has been organised with a view of checking the excessive infantile mortality which constitutes so great a blot on modern civilisation. Contributions may be sent to the Treasurers, of whom one is Mr. C. C. Wakefield, Sheriff of the City of London, Stafford House, Cannon Street, London, E.C.

⁂

WE have been favoured with a copy of the *Ophthalmoscope* for April. It contains a number of illustrations, all reproduced in the best possible style. Indeed, the Editors may be congratulated on having eclipsed all previous issues in the amount and the high standard of the contributions. Dr. Sinclair Thomson begins with an interesting article on the frequency of orbital manifestations of nasal sinusitis. This is followed by another on the ocular and orbital complications of disease of the accessory nasal sinuses by Dr. Jameson Evans, of Birmingham. Dr. Fish, of Chicago, contributes a learned notice of thirty-six consecutive cases of optic neuritis. Mr. Sidney Stephenson describes three cases of malignant disease of the accessory sinuses, with some specially good plates of microscopical sections. The abstracts of special articles relating to ophthalmology is wide and varied. It may be said of this journal that its 111 pages are full of excellent matter, and the production is most creditable to medical journalism in this country.

LABORATORY NOTES.

SOME NEW DRUGS.

THE well-known firm, Messrs. A. and M. Zimmermann, have lately introduced some new drugs and new preparations of old drugs which are sure to have a patient trial from those who are acquainted with the firm's products. One interesting novelty is a synthetic camphor prepared by Messrs. Schering, which appears, from the observations of Professor Langgaard, of Berlin University, and of Professor Grawitz, of Charlottenburg Hospital, Berlin, to be identical with natural camphor in all chemical and therapeutical respects, but it has this additional advantage—that it is capable of being manufactured now at a rate lower than that of the natural article.

Cellotropin (mono-benzol-arbutin) is a drug which appears to act on the principle of increasing the number of tuberculous anti-bodies in the blood, and thereby assists the organism to overcome tuberculosis by a natural method of cure. Herbanin is an iron preparation which is derived from vegetable sources. It is said to have a pleasant taste, not to injure the teeth, not to disturb the digestion, nor to cause constipation. As, moreover, the reports of the benefit derived from it in cases of chlorosis and similar affections are very favourable, probably medical men will be glad to give it a trial.

The history of Nastin, another of these new drugs, is a little remarkable. Professor Deycke, of Hamburg, was experimenting with leprosy, and was struck by the numbers of a certain streptothrix which appeared in cultures. Cultures of this organism seemed to benefit leprous patients when injected hypodermically, and further trial showed the value to depend on the presence of certain fatty substances, to which the name "Nastin" has been given. These bodies were isolated and used and now the Nastin is put up into tubes containing a crystallisable and neutral fat (ester of glycerine), combined with a benzoyl-chloride, and called Nastin-B. Its credentials cannot be set aside.

A new weapon is placed before us in the treatment of diseases of the bladder in Fomitin, which is made by extraction from two plants parasitic on the plum tree, namely, *Hymmomycetin fomes* and *Fomes igniarius*. Fomitin is a reddish-brown, rather bitter liquid, with mushroom-like smell. It has been employed with advantage, it appears, not only in diseases of the bladder, but in dysmenorrhœa, menorrhagia, and hæmorrhoids.

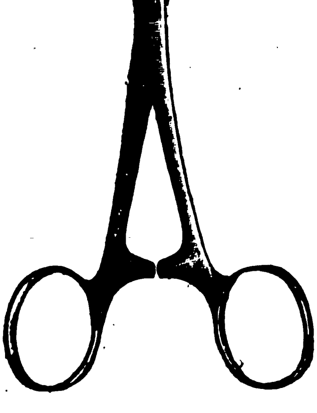
Finally, in Bilitin the firm think they have a specific for gall-stones, and if further trial warrants the conclusion, it will be a good day for everybody when it is established as such. The present remedies for gall-stones are far from being "specifics."

THE Bayer Company, Limited, are introducing a drug named novaspirin to the notice of the profession. It is claimed that novaspirin passes unchanged through the stomach and is free from any risk of gastric disturbances, and that in the intestines it decomposes into nascent salicylic acid and methylene-citric acid, without giving rise to irritation or unpleasant by-effects. Chemically, novaspirin is methylene-cytril-salicylic acid. It is a white, odourless powder of faint acidulous taste, easily soluble in alcohol, soluble with difficulty in chloroform and ether, and almost insoluble in water. It contains 62 per cent. of salicylic acid. One of the indications for its use lies in influenza, in which it has been found to relieve the pains, to reduce the fever, and in general to promote the comfort of the patient. It is also useful in the treatment of coryza, tonsillitis, pleurisy, neuralgia, nervous headaches, tabes and carcinoma. The administration of novaspirin is not followed by profuse perspiration, because the drug is absorbed so slowly, a matter of importance when diaphoresis is not desired, as in cases of weak patients, grave cardiac affections, chronic wasting diseases, and danger of severe hæmorrhages, nor has ringing in the ears been observed to follow the use of the drug. It is an efficient and agreeable remedy in the various forms of rheumatism, both articular and muscular, as well as in gouty conditions. The average dose for adults is 15 gr. several times a day. This may be increased to 30 gr. in rheumatic and gouty troubles. Owing to its insolubility in water it is best administered in powders, wafers, or in the form of tablets.

MILK OF MAGNESIA (PHILLIPS').

THIS compound is by way of being a model of elegant pharmacy. It is well-known in America under the name of Phillips' milk of magnesia, and latterly its admirable properties have become appreciated on this side of the Atlantic. It is useful in all cases where the administration of alkalies is indicated, and a special field of usefulness is claimed in morbid conditions connected with uric and lactic acid. There is always room for a really good preparation of magnesia for children, and the nursery could hardly be provided with a better one than that under notice, which we have put to a practical test and found to answer the claims put forward on its behalf.

A NEW TONGUE FORCEPS.



DR. RODERICK, of Cambridge, has devised an improved clip to pull the tongue forward during the administration of an anæsthetic. It consists of Spencer Wells' handles and catch with Liston's Artery Forceps Blades, slightly arched outwards so as to allow for the thickness of the tongue. Compared with the ordinary tongue clip, which compresses a considerable area of tongue tissue, thus causing pain and discomfort to the patient for several days, this instrument only produces a minute puncture, which soon heals up. The makers are Messrs. Arnold and Sons, West Smithfield, London.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Calcified Fibroma of the Ovary.—Casalis (*Journal of Obstetrics and Gynæcology of the British Empire*, April, 1908).—Under this heading the details of a rare condition are given. The patient, a fat, coloured woman, æt. 42, sought advice and treatment for menorrhagia and metrorrhagia, accompanied by severe pains in the lumbar and hypogastric regions. The pains had become continuous, and the patient was seldom more than a week free from hæmorrhage. Examination proved the presence of a fibroma of the uterus, and what was thought to be a second pedunculated growth rising from the fundus uteri. On opening the abdomen an ordinary interstitial fibroma invading the whole uterine body was found about the size of a cocoanut. The pedunculated tumour proved to be a calcified left ovarian fibroma as big as a cricket ball, quite distinct from the uterine tumour to which it preserved its usual relation. This ovarian growth was white and stonelike on section being made by a fine saw, showing complete infiltration with lime salts. The capsule was fibrous, and practically no other fibrous tissue was present. The Fallopian tube was hypertrophied, but otherwise normal. The weight of the ovary was 1 lb. 4 oz. The right ovary, though microcystic, and the right tube, were left. H.

A Case of Chancre of the Cervix Uteri.—Ivens (*Journal of Obstetrics and Gynæcology of the British Empire*, April, 1908).—A report of a case is given, occurring in a married woman, æt. 32, who complained of backache. She was a iv.-para. The first child was stated to have died of "consumption of the bowels"; the second was still-born; but the remaining two were healthy. The patient had been in good health until three months prior to her coming under observation, when she had consulted a doctor for backache, and a Hodge pessary had been inserted for its relief. Micturition for a few weeks had been painful and frequent, with some blood. Husband had recently been treated for a "discharge." A blood-stained purulent discharge was noticed on examination. There was no ulceration of the vulva, and no enlargement of the inguinal glands. The uterus retroverted, but movable. The external os somewhat patulous, and an ulcer the size of a shilling situated slightly to the right side of the cervix, but extending over both lips, was discovered covered with a grey slough and having an indurated base. A linear ulcer was found in the urethra near the neck of the bladder, and the mucous membrane intensely congested. The author believes this latter condition to have been due to gonorrhœa, but no microscopical or bacteriological examination was made. The cervical ulceration suggested malignancy, but was more typical of syphilis. A small portion was excised for examination, which showed the surface of the ulcer to consist of exudation and necrotic granulation tissue, the connective tissue to be hyperæmic and densely infiltrated with round cell and extreme cellular proliferation, the intima of the vessels being thickened. The treatment consisted in antiseptic douching while waiting for secondary symptoms to appear. Five weeks later typical secondary symptoms appeared, sore throat, etc. The cervical ulcer looked cleaner, but was in no way diminished. Mercurial treatment, general and local, was adopted, and in a few weeks the sore throat disappeared, and in three weeks' time the chancre had gone. The urethra was treated with nitrate of silver. The author points out the great difference of opinion among gynæcologists as to the frequency of the occurrence of chancre of the cervix, Sir W. Japp-Sinclair believing it to be extremely rare, McCann stating that it is not rare, while Pernet, supporting McCann, quotes Fournier, who found 13 cases out of 249 cases of genital chancre. H.

Ear Disease in Infancy and Childhood.—Kenefech (*Amer. Jour. Obst.*, April, 1908).—The otitis of children may be roughly divided into two classes—the first arising within the tympanum from causes brought to it by morbific agents in the circulating blood; and, second, those comprising infectious processes set up by inflammatory and congestive conditions in the immediate neighbouring structures. The first class is associated with some concomitant general disease, such as syphilis or tuberculosis; the second embraces by far the greater number and most frequently met with—*i.e.*, hypertrophied lymphoid tissue in the pharyngeal vault and hypertrophied and diseased faucial tonsils. An adenoid mass, both on account of its own circulation and the pressure it causes on the neighbouring structures, keeps up at the mouth of the Eustachian tube a constant vascular engorgement which extends to the tympanic cavity and its contents as well. There is another class of case in which adenoid growths within the fossæ behind and above the Eustachian cushion seriously impede physiological action of the muscular structures of the Eustachian cushion concerned in opening and closing the pharyngeal tubal orifice. While the child is in the upright position by day, this growth gives scarcely any evidence of its presence, but at night it becomes engorged even to the extent of impeding respiration, producing damage to the general health and special harm to the hearing apparatus. To treat acute cases of otitis so that the process may be checked, the tympanic membrane preserved intact, and its function restored, the writer's practice, when the diagnosis of acute otitis is made, is to slit, not pierce, the drum posteriorly, and thus drain from the lowest point. This is done whether or not spontaneous rupture of the tympanic membrane has occurred. Irrigation frequently with salt solution is followed by healing, in most cases, in from ten days to two weeks. The naso-pharynx and fossæ of Rosemüller should be cleared out as soon as the age and strength of the child will allow. F.

Symptoms, Diagnosis and Treatment of Tubal Gestation in the Early Weeks.—Tate (*Brit. Med. Jour.*) considers there is an increasing frequency in this form of gestation, symptoms usually commence before the tenth week, most commonly from the third to the eighth week, and their onset is usually an indication of some change taking place in the gestation sac, *e.g*, hæmorrhage. The typical symptoms are often absent, although two symptoms are invariably present, irregular hæmorrhage and attacks of abdominal pain, amenorrhœa was present in only 56 per cent. of cases. The conditions most commonly mistaken for tubal gestation are pelvic inflammation and ordinary miscarriage. As regards treatment, operation is indicated when hæmorrhage is moderate or severe, and of recent origin, and when symptoms and physical signs indicate that the gestation sac is still within the tube, when a hæmatocele has already formed, and when the patient has been free from any symptoms for a week after the initial attack of pain, expectant treatment is safe. F.

The Induction of Labour for Visual Indications.—Pooley (*Amer. Journ. Surg.*, March, 1908).—The changes in the eye in the albuminuria of pregnancy are essentially the same as in chronic nephritis. These may be (1) a sudden, more or less transitory or complete loss of sight, without appreciable changes in the fundus oculi; (2) a gradual failure, with characteristic changes in the retina and optic nerve, which in time may lead to blindness. Evidence of disease of the kidneys not infrequently show themselves in the eye before they do in the urine. In uræmic amaurosis, without changes in the eye visible to the ophthalmoscope, even should the usual symptoms, dizziness, nausea, and threatened convulsions be absent, their occurrence is soon to be feared, and labour should be induced without waiting until the life, as well as the sight of the patient is in danger. Prognosis as to the recovery of vision is better in cases in which chronic nephritis does not already exist. F.

Dysmenorrhœa Membranacea.—In the opinion of Hitschmann and Adler (*Monatssch. für Geb. und Gyn.*, Bd. XXVII., Hft. 2) dysmenorrhœa membranacea is not an exfoliative endometritis. It is a type of menstruation in which the usually detached portions from the surface of the endometrium assume greater dimensions. The predisposition to this lies in the special development of the menstruating mucous membrane, real or relative, narrowness of the os internum favours obstruction, and thus uterine contractions are set up which cause pain and perhaps further separation of the mucous membrane. The cases of dysmenorrhœa membranacea are only a small group in the great province of dysmenorrhœa. On the other hand, while we know practically nothing about the ætiology of the other forms of dysmenorrhœa, the picture of dysmenorrhœa membranacea revealed by the author's investigations is fairly clear. Since there is no endometritis, curettage is useless, and therefore not to be employed. We can only rely on palliative treatment of which the authors prefer the systematic premenstrual dilatation of the os internum. G.

Rest in Bed During the Puerperium.—F. Martin *Monatssch für Geb. und Gyn.*, Bd. XXVII., Hft. 2), to estimate the advantages which, according to Küstner, are associated with early rising from bed during the puerperium, experimented with one hundred lying-in women. By this early rising he only means that the patient sits up quietly out of bed with a tight binder on the abdomen. The women were chosen without considering the number of their previous labours or their age. Those who were not considered fit for the treatment were patients who had had prolonged labour, intra-partum fever, operations, injuries, or when there was disease of the heart, lungs, kidneys, or blood vessels. The women got up for the first time 15 to 24 hours after labour was completed. During the next seven days they were out of bed for two hours in the forenoon and two hours in the afternoon. The puerperal morbidity was 13 per cent. Involution of the uterus was normal in every case and in no case was ergot necessary. The uterus on the seventh day was always found anteflexed. There was no case of embolism among the hundred cases nor among another series of eight hundred treated in a similar manner. The author can, therefore, recommend this treatment when one can be, as far as possible, certain that no infection occurred during labour and the time at the disposal of the mother for recovery after labour is short. As regards well-to-do people, one can conclude that it is not necessary to keep healthy women lying for as long a time as formerly, and that we can more often put them in a different position when they feel well enough.

Medical News in Brief

The British Association for the Advancement of Science.

The Executive Committee, which is making preparations for the meeting of the British Association to be held in Dublin in September next, is inviting subscribers and guarantors to come forward in order to meet the necessarily large expenses which must be incurred. It is estimated that a sum of at least £3,500 to £4,000 will be required, and of this more than half has been already promised. The work of the Society will be transacted in twelve sections, which, with their respective Presidents, are as follows:—Mathematical and Physical Science.—W. N. Shaw, F.R.S. Chemistry.—Professor F. S. Kipping, F.R.S. Geology.—Professor J. Joly, F.R.S. Zoology.—S. F. Harmer, F.R.S. Geography.—Major E. H. Hills, R.E. Economic Science and Statistics.—W. M. Acworth, M.A. Sub-Section, Agriculture.—Right Hon. Sir Horace Plunkett, K.C.V.O., F.R.S. Engineering.—Dugald Clerk, M.I.C.E. Anthropology.—Professor W. Ridgeway, M.A., D.Litt. Physiology.—J. S. Haldane, F.R.S. Botany.—F. F. Blackman, F.R.S. Educational Science.—Professor L. C. Miall, F.R.S. These sections will meet at Trinity College, the Royal University, the Royal Colleges of Physicians and Surgeons, the Royal Irish Academy, and the Royal Dublin Society. The reception-rooms and administrative offices will be situated in Trinity College. Amongst the social functions which have been already arranged are garden parties by their Excellencies the Lord Lieutenant and the Countess of Aberdeen, by Lord and Lady Ardilaun, and by the Provost and Senior Fellows of Trinity College. Evening receptions are also to be held by the Viscount and Viscountess Iveagh, and by the Royal Dublin Society. The Lord Mayor and Lady Mayoress will be "At Home" at the Mansion House to members of the Association on the afternoon of the opening day of the meeting.

Trinity College, Dublin, School of Physics—Post-Graduate Classes.

The first classes in Ireland for systematic post-graduate instruction were established by Trinity College four years ago. Since then Trinity College has given each summer a three weeks' course, open to all qualified medical men. This year, in addition to the summer course, which will be held from June 8th to June 27th, there will be an autumn course from September 21st to October 10th. The subjects dealt with include Medicine, Surgery, Gynæcology, and special departments such as Diseases of the Skin, Throat, Nose, Ear and Eye. There are also classes in Pathology, Physiology, Anatomy, Cystoscopy and X-ray work. The time-table is so arranged that each member can, if he desires, attend all the classes. The hospitals embraced in the scheme are within easy walking distance of Trinity College, so that little time need be lost in going from one institution to another. As in former years, arrangements have been made by which a limited number of members of the class can reside in college rooms and dine on commons. Further particulars, including expense of course, will be found in our advertising columns. A syllabus can be obtained from the hon. sec., Dr. Parsons, 27, Lower Fitzwilliam Street, Dublin.

Royal College of Surgeons.—Post-Graduate Courses.

We publish in our advertising columns particulars of the two post-graduate courses which the President and Council of the Royal College of Surgeons have arranged to conduct during the months of June and September. The object of these courses is to render available the whole of the clinical material in the City for the post-graduate student, so that he may see as much as possible during the brief time at his disposal. The intending student will note from the list of hospitals that this object has been accomplished, seeing that the ten general hospitals are included, as well as the various hospitals devoted to special subjects. Those conducting the courses will be careful to make them as practical and helpful to the varying needs of the practitioner as possible. In the event of the post-graduate students exceeding a certain number at either of the courses, arrangements will be made to divide up the classes into practical working groups.

The New Irish Universities.

The draft charters of the new Universities have been issued during the past few days. One of the most interesting paragraphs relates to the appointment of Professors in the constituent colleges. The Senate of the University to be formed in Dublin will have the appointment of these Professors, subject to the following conditions:—

(*a*) In the case of a Professorship or Lectureship of a constituent College, to which the University, by the Charter or Statutes of the College, is entitled to appoint, the Senate must invite and consider the representations of the governing body of the College as to the filling of the vacancy; and if the number of candidates be more than three, the governing body of the College shall be entitled to select not less than three candidates from amongst whom the Senate must make the appointment.

(*b*) The Senate must in every case obtain and consider the advice of the General Board of Studies given upon a report which that Board must obtain from the Faculty to which the vacant Professorship or Lecturership belongs.

It remains to be seen how far this arrangement will meet the views of the representatives of the constituent Colleges in Cork and Galway, and it is already evident that the degree of autonomy possessed by these Colleges will be a matter for some considerable discussion.

The names of the Senates of the two Universities have also been published, and amongst them we find those of many well-known medical men. In the case of the University in Dublin, Dr. D. J. Coffey, M.B., is named as the President of the Dublin College, and on the Senate are Sir C. Nixon, Bart., M.D., Drs. Cox, McArdle, O'Carroll, P. A. O'Sullivan, C. Y. Pearson, J. P. Pye, Sigerson, B. C. Windle (President of the Cork College). In the case of the University in Belfast, the followng names appear in the list of the Senate: Drs. Johnson Symington (Registrar), P. R. O'Connell, Sir William Whitla, Drs. T. Sinclair, J. W. Browne, P. Redfern.

"Medical Specialist."

LAST week, before Mr. Horace Smith, Bertram Mortimer, *alias* Henry Sylvester, described as "Professor" Mortimer, medical specialist of Berkley College, Boston, U.S.A., and his son, Herbert Sylvester, student, of the same town, were brought up in custody, the first-named in charge of a warder from Exeter, accused of being concerned together in stealing a portmanteau and contents, value £10, from the Victoria Station of the London, Brighton and South Coast Railway.

The elder prisoner had been committed for trial from Exeter charged with obtaining money by false pretences. It was stated in evidence that on April 2nd a gentleman, an X-ray specialist, left his portmanteau in the cloak-room at Victoria. The valise was, by a porter's mistake, handed over to a person who produced a ticket relating to another deposit—two parcels tied together. This last-mentioned property was claimed by and subsequently given up to the elder prisoner. On the part of the prosecution witnesses were called to prove that both the prisoners were at different times in possession of the prosecutor's bag and its contents. It was found at the younger prisoner's lodgings at Swansea by Inspector Badcock, of the railway police.

The defendants cross-examined at great length, and, after a long hearing, the prisoners were remanded.

Royal College of Surgeons in Ireland.—General Meeting and Election of Officers.

A MEETING of the College will be held on Saturday, May 30th, at 1 o'clock, to receive the annual report of the Council. Notices of motion received by the Registrar on or before Tuesday, May 19th, will have priority of consideration over any others which may be submitted. A meeting of the College will also be held on Monday, June 1st, at 1 o'clock, pursuant to the provisions of the charters, to elect a President, Vice-President, Council and Secretary of the College for the ensuing year. Fellows who may desire to have their names printed on the list of candidates for office will please signify their wish by letter to the Registrar, at the College, on or before Tuesday, May 19th, as it is necessary to include the names in the voting papers which are forwarded to the Fellows, and no candidate is eligible unless his application is received within the date specified.

PASS LISTS.

The Royal University of Ireland.—Medical Degrees Examinations.

THE following candidates have passed the Third Examination in Medicine:—Upper Pass.—*George Cooper, William Hamilton, B.A., Arthur V. J. Harrison, *Melville C. Irwin, Denis Lynch, *John M. McCloy, John P. J. McGivern, *Walter Mooney, B.A., *Charles J. Simpson, *William W. D. Thomson, B.A. (Those marked with an asterisk may present themselves for the further examination for Honours.)

Pass.—William Boyd, Francis J. Burke, James Byrne, Patrick J. Campbell, John B. Crawford, Patrick J. Cullinane, John J. Dennehy, Michael G. Devine, Edmund Doherty, George S. Glass, B.A., William E. Graham, John L. Jackson, Sarsfield P. Kerrigan, Bertram C. Letts, Barkley McCullough, B.A., Thomas P. McMurray, Harold D. Manderson, Michael Moloney, Henry C. Mulholland, William M. J. O'Connor, Joseph E. O'Sullivan, William Prendivale, Alfred H. Rentoul, Thomas W. Ruttledge, Gerard Sheridan, Rupert A. Smith, Bernard Teeger, Robert W. Vint, Espine F. Ward, Timothy Woulfe.

THE following candidates have passed the undermentioned examinations:—

The M.B., B.Ch., B.A.O. Degrees Examination.—Upper Pass.—Donal Barry, Arthur R. Boyd, Thomas A. Carson, James K. P. Clarke, Thomas J. Hollins, B.A., Marshall F. Huston, Joseph G. Johnston, Arthur H. Joy, Robert G. Kevin, Thomas P. Linehan, George H. Martin.

Pass.—Thomas Arnold, Raphael N. Berman, William Bradbury, Thomas G. Buchanan, Robert J. Clarke, Mary Cowhy, B.A., Edmund H. Flanigan, William S. Graham, Hugh J. Grant, Patrick J. Grogan, Richard G. C. M. Kinkead, Robert J. Leslie, Solomon Levy, John C. Macaulay, Joseph McCausland, B.A., Michael McNiff, James F. Neary, John F. Neary, John F. O'Brien, Michael Waldron, George P. White, Michael White.

The following candidates may present themselves for the further examination for Honours in the groups set after their names:—Donal Barry, Medicine and Surgery; Arthur R. Boyd, Medicine; Thomas A. Carson, Medicine; Thomas J. Hollins, B.A., Midwifery; Marshall F. Huston, Medicine; Joseph G. Johnston, Medicine and Midwifery; Arthur H. Joy, Surgery; Robert G. Kevin, Medicine and Surgery; Thomas P. Linehan, Surgery.

The M.D. Degree Examination.—Pass.—James G. Campbell, M.B., B.Ch., B.A.O.; William H. Davis, M.B., B.Ch., B.A.O.; Joseph P. Dee, M.B., B.Ch., B.A.O.; Denis J. Keane, M.B., B.Ch., B.A.O.; Thomas D. Luke, M.B., B.Ch., B.A.O.; William Rice, M.B., B.Ch., B.A.O.; John Thompson, M.B., B.Ch., B.A.O.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

THE following candidates have passed the Second Professional Examination, April, 1908:—F. W. Warren (with honours), A. A. Russo (with honours), T. M. Thomson (with honours), R. J. Barlee, J. Brereton Barry, D. F. Curran, C. A. Farrell, E. E. Holden, J. T. Hill, A. Kennedy, L. A. Moran, T. J. McDonnell, P. J. O'Reilly.

Faculty of Physicians and Surgeons of Glasgow.

AT the recent examinations of the Board of the Royal Colleges of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow, the following candidates passed their respective examinations:—

Five Years' Course—First Examination.—Arthur L. Edwards, James A. Frost, George A. Macvea, Cyril S. Owen, William Shorten, Valentine H. Wardle.

Second Examination.—John Paxton, Hugh F. Williams.

Third Examination.—Conrad J. Arthur, Herbert C. Bankole-Bright, Denis Cogan, James D. Collins, John A. Irwin, Angus C. Livingston, Patrick J. Taaffe, Frank W. White.

Final Examination.—Ishwar Das, Punjab; Charles J. C. Faill, William R. Griffith, Maurice E. Kayton, James W. M. Hunter, Les S. Machado, Ceylon; John M. Muir, Manec B. Patel, Bombay; Sécossène Piarroux, Mauritius; Patrick Reid, Bildev Singh, Lahore.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTICEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Cigaretto.—There are several organisations of the kind, but we believe the one you refer to is called The British Anti-Tobacco and Anti-Narcotic League. We understand that members can also pledge themselves against drinking, gambling, and profane language; but we are not in a position to state this from personal knowledge.

A BRASS HEART.

The latest triumph of surgical skill is a mechanical brass heart, which enables a man to go on living when without it he would be dead. The heart is invented by an American professor. Now the gentleman's silly old heart can take a rest when ever it likes, for the professor has only to fix the double tubes to the larynx and nose of the patient, set the pumping arrangement at work, and the otherwise dead gentleman will soon be all alive and possibly kicking. The professor himself managed to stop breathing for ten minutes—the onlookers thought his demise was as satisfactorily completed as that of Queen Anne, but he had a card up his sleeve. He touched the button, or took the necessary steps to set the brass heart beating. Away went the machinery, pumping life-giving oxygen into the learned gentleman, and in a very short time he sat up, noticed things, and then remarked to the folk who were about to buy wreaths, "Got the grin of you this time, I guess." And it was so. He is now scheming solid wooden heads for public men, and great results are anticipated.—*Morning Leader*.

Norwich.—Unfortunately, your city does not enjoy an envious reputation for salubrity. We have been informed by an authority, who should know something of the locality, that the nature of the soil is a factor in the higher death-rate when compared with towns similarly situated, but of this we have no personal knowledge. According to the Registrar-General's return, the mortality last week in Norwich was 23.3 per 1,000 of the population. In London it was only 14.7.

Meetings of the Societies, Lectures, &c

Wednesday, May 6th.

Royal Society of Medicine (Neurological Section) (20, Hanover Square, W.).—8.30 p.m.: Papers:—Sir William Gowers, F.R.S.: The Mechanism of Nystagmus. Dr. E. Farquhar Buzzard: A Note on the Occurrence of Muscle Spindles in Ocular Muscles.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. J. Clarke: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. E. T. Collins: Convergent Strabismus.

Thursday, May 7th.

North-East London Clinical Society (Prince of Wales's General Hospital, Tottenham, N.).—4.15 p.m.: Clinical Cases.

Harveian Society of London (Paddington Green Children's Hospital).—8.30 p.m.: Clinical Evening.

Ophthalmological Society of the United Kingdom (11, Chandos Street, Cavendish Square, W.).—8 p.m.: Mr. E. E. Henderson, Mr. E. Green, Mr. C. Hailes, and Mr. J. H. Tomlinson: Card Specimens. Dr. F. Fergus: Ptosis Operations. Mr. E. Clarke and Sir A. Wright: Tubercle of the Choroid cured by Tuberculin Mr. E. Clarke and Mr. S. Mayou: Tubercle of the Iris cured by Tuberculin. Mr. P. E. H. Adams: An Epidemic of Contagious Conjunctivitis due to the Pneumococcus. Dr. G. Mackay: (1) A Case of Arterio-venous Aneurysm treated by Ligature of the Common Carotid; (2) A Case of Phlyctenular Keratitis and Pustular Episcleritis treated by Antistaphylococcic Injections.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Sir Malcolm Morris: Pruritus Ant.

Friday, May 8th.

Royal Society of Medicine (Clinical Section) (20, Hanover Square, W.).—8.30 p.m.: Cases:—Mr. Watson Cheyne: Spontaneous Disappearance of Recurrent Carcinoma of Breast. Sir Thomas Barlow and Mr. C. A. Ballance: Suture of the Brachial Plexus for Birth-palsy. Dr. Purves Stewart: Meningo-cortical Lesion illustrating Astereognosis. Dr. J. Barnes Burt: Three Cases of Gout showing Destructive Changes in Bone. Mr. C. H. Fagge: (1) A Case in which for Recurrent Sarcoma Parts of the Femoral Artery and Vein were Excised; (2) A Case of Aneurysm of the Common Femoral Artery, Excision of Aneurysm and of the Common Femoral Vein. Dr. G. A. Sutherland: Scleroderma. Mr. Albert Carless: Multiple Diffuse Lipomata. Mr. P. Maynard Heath: Caries of Spine with Clubbing of Fingers and Toes. Short Papers:—Mr. C. A. Ballance: A Case of Arterio-venous Anastomosis for Senile Gangrene. Dr. Norman Dalton: A Case of Leucoderma dying with Symptoms of Addison's Disease.

Society for the Study of Disease in Children (11, Chandos Street, Cavendish Square, W.).—5 p.m.: Dr. O. K. Williamson, Dr. Carpenter, Dr. P. Parkinson, Mr. Lett, Mr. R. Howard, and others: Cases and Specimens. Dr. W. Ewart: The Empty Bronchus Treatment by Posture in the Bronchiectasis of Children.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. S. Stephenson: Clinique. (Eye.)

Appointments.

Mill, G. Robertson, M.D.Edin., Honorary Medical Officer to the Birkenhead Maternity Hospital.

Reese, David William, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer of Health by the Warmley (Gloucestershire) Rural District Council.

Vacancies.

Glamorgan County Asylum, Bridgend.—Junior Assistant Medical Officer. Salary, £150 per annum, with board apartments, attendance, and washing. Applications to the Medical Superintendent.

Bucks County Lunatic Asylum.—Assistant Medical Officer. Salary, £150 per annum, with board and furnished apartments in the Asylum. Applications to the Medical Superintendent, the Asylum, Stone, Aylesbury.

Clinical Research Association.—Assistant Director of the Laboratory. Salary, £250 per annum. Applications to the Secretary, Clinical Research Association, Ltd., Watergate House, Adelphi, W.C.

Nottingham City Asylum.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, etc. Applications to the Medical Superintendent.

Lincoln General Dispensary.—Resident Junior House Surgeon. Salary, £175 per annum, with furnished apartments, fire, and gas. Applications to the Secretary, R. H. Lynn, 2, Bank Street, Lincoln.

King Edward VII. Sanatorium, Midhurst, Sussex.—Senior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and attendance Applications to the Hon. Secretary, 19, Devonshire Street, Portland Place, London, W.

Carlow District Asylum.—Resident Medical Superintendent. Salary £350 per annum. Applications to John Keenan, Secretary, Joint Committee.

Benenden Sanatorium.—Medical Superintendent. Salary, £250 per annum, with board, lodging, and attendance. Applications to the Secretary, 54, Gray's Inn Road, London.

London County Asylum, Horton, Epsom, Surrey.—Assistant Medical Officer. Salary, £150 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6, Waterloo Place, London, S.W.

Births.

Toland.—On April 30th, at 18, Addington Road, Bow, London, the wife of C. K. Toland, M.B. (Hilda Bush), of a son.

Marriages.

Dodwell—Robertson.—On April 30th, at All Saints', Upper Norwood, Philip Rashleigh Dodwell, M.D., to Jessie, widow of Lieut.-Colonel F. W. Robertson, Royal Sussex Regiment.

Harris—Taylor.—On April 29th, at St. Edmund's Church, Rochdale, Herbert Harris, M.D., of Wellfield and Oaklands, Rochdale, to Edith Maud, only daughter of Edmund Taylor, of West Bank, Rochdale.

MacGregor—Brittan.—On April 30th, at St. Cuthbert's, Philbeach Gardens, Alexander Pendarves, son of James MacGregor, sometime Chairman S.E. Rly., and M.P. for Sandwich and Deal, to Mabel, younger daughter of the late Frederick Brittan, M.D., Clifton and Gwynfryn, Cardiganshire.

Welsh—Hearn.—On April 29th, at St. Michael's Church, Bray-on-Thames, Alfred P. Welsh, Alberta, Canada, to Edith Anne Olivin (Ida), youngest daughter of the late George M. Hearn, M.D., Woodville, Bawnboy, co. Cavan.

Deaths.

Beatty.—At Rockfell, Sutton, on April 30th, Frances Eleanor (Fanella), wife of Wallace Beatty, M.D., 38, Merrion Square, Dublin, and daughter of the late Samuel Edge, M.D., Granstown House, Queen's County.

Ellis.—On April 29th, at Halford House, Attleborough, Carteret George Ellis, L.R.C.P., M.R.C.S., aged 88.

Littlewood.—On May 2nd, at The Ropewalk, Nottingham, Joseph Littlewood, J.P. and M.R.C.S.

Newington.—On April 30th, at Uxbridge, John Siddle Newington, M.B., C.M., L.S.A., son of the late Robert Samuel Newington, M.R.C.S., L.S.A., of Gonahurst, aged 45 years.

Torry.—On May 1st, John Cooper Torry, M.D., M.R.C.P. Deeply mourned.—In Memoriam: In loving memory of Sarah, wife of the above, who died Oct. 25th, 1897.

"A distinct advance on Easton's Syrup."

—The Lancet.

"Bynin" Amara

'BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, therefore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

COMPOSITION.

Quinine Phosphate	1½ grains.
Iron Phosphate	2 ,,
Nux Vomica Alkaloids equal to Strychnine	$\frac{1}{16}$,,
'Bynin, Liquid Malt	1 ounce.

DOSE FOR ADULTS—One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, MAY 13, 1908. No. 20.

NOTES AND COMMENTS.

An Indignant Authority. IT is good to know that the fine old race of high Tory who objects to innovation in principle is not yet extinct, as it exercises a drag on the feverish progress of a restless age. We recollect with satisfaction that when the question of medical inspection of school-children was before Parliament, even in the highly-contentious Education Bill of 1906, not a soul was found in either House to oppose the clause enjoining on local authorities the duty of providing for such inspection. But the representatives of the nation reckoned without the Glendale Rural District Council. This important body has recently had under consideration the duty thus inconsiderately thrust upon it, and indignantly it recoils from the imposition. "The members of this Council," runs a resolution unanimously carried, "view with extreme disfavour the proposals of the County Education Committee with regard to the medical examination of children. They consider such a system would entail a large and useless expenditure of the ratepayers' money; they think it would be distasteful to very many of the parents; and they are, moreover, of opinion that if Parliament makes such an order, the funds to pay for the working of it should be provided out of the Imperial Exchequer, and not out of local rates. They hope the County Council will not adopt the proposal, and suggest a strong protest should be sent to Parliament against such a method of legislating." Thus speaks the thorough-going reactionary. We agree with the Glendale Rural District Council that innovation *quâ* innovation is to be resisted; but what a fine spectacle the gallant little body makes thus brandishing its oratorical fireworks in the face of the Mother of Parliaments!

Glendale contra Mundum. FAR be it for us to suggest a course of action to this indignant body, bleeding from St. Stephen's rods, but we can hardly imagine that the Front Benchmen on either side will be even as much impressed by this fiery protest as by the intimidating tactics of the Women's Social and Political Union. Still, there are times when "wisdom's triumph is well-timed retreat," and, considering the healthy state of public opinion which has been created in this subject, we fancy the Glendale Council would consult its own reputation best by pocketing the indignity which it is called upon to face, and submitting to the distasteful inevitable. There is much significance in the fact that educational authorities all over the country have gladly welcomed the addition to their burdens which the medical inspection of children entails. Though they have generally, in our opinion, followed a short-sighted policy of economy in the matter, they have only taken their marching orders from the Education Board which set its face so firmly against making medical inspection what it should be, namely, a dignified and fully-effective instrument for promoting the health and physical development of the rising generation. To make the service of medical officers to schools a subordinate one, catering only for recently-qualified men, and offering them no prospects, is an error that may yet bring the glow of triumph to the cheek of Glendale Rural District Council.

Crowner's Law. A MOST unpleasant incident occurred at Grantham last week. Dr. Sidney Firth, of that town, had under his care a three-months-old child whose mother had previously been attended at her confinement by a midwife, and on the child's death he gave a certificate to say that death was due to "premature ligature of the umbilical cord by an unqualified midwife." The Registrar refused the certificate and communicated with the Coroner, who ordered an inquest, detailing two other medical men to make the post-mortem. These gentlemen found that the umbilicus was healthy, but that the child had died of pneumonia. From the report of the case it is not quite clear if Dr. Firth was in agreement with his colleagues, and, if in agreement, he considered the pneumonia was due to any septic or other trouble connected with the cord. However, when asked in Court why he gave the certificate in the form quoted, he said he thought the matter ought to be brought to notice, and also that it was a subject to which he had given special attention in the course of 4,000 confinements attended by himself. Therefore, whether actually right or wrong, nothing surely could be plainer than that he acted in good faith and for the public good. The Coroner, however, accused him of the offence of giving a false certificate of death, and, in spite of Dr. Firth's protest, refused to withdraw the expression.

The Autocrat at the Inquest. IT is difficult to write with patience of such conduct on the part of the Coroner. That a petty official is given free licence to insult in the grossest manner a member of a learned profession, even assuming for the sake of argument, a mistake had been committed, is intolerable; and still more so that there is no remedy. The misuses of the coroners' position have gone beyond all bounds, and the need for appeal against their censures and their conduct is urgently needed. We believe coroners are the only judicial officers whose decision is final. By a curious constitutional anomaly they are independent persons responsible to nobody, except in a shadowy way to the Lord Chancellor. Even the judges in the

House of Lords can only arrive at a judgment when three members are sitting together, and the Lord Chancellor himself is responsible to Parliament. But the coroner, who is often a local man of no particular education or prestige, is a law unto himself, and before his authority everyone must bow. When the subject of death-certification is before Parliament, as it is bound to be sooner or later, the powers of these functionaries must be closely investigated—and curtailed. Unlimited power is good for no man, and it is not a little extraordinary that the coroner's should be, perhaps, the only position under the Crown which has escaped democratisation.

Fortunes in Medicines.

The will of Mr. A. B. Scott, senior partner in Messrs. Scott and Bowne, Ltd., proprietors of Scott's Emulsion, was proved last week at £174,947 in England, and 55,000 dollars in America. These handsome sums were accumulated, presumably, chiefly through the profits on the emulsion which bears the owner's name, and the circumstance has produced many comments on the fortunes which attend on advertising businesses in drugs and proprietary preparations of foods. With Mr. Scott's fortune have been compared those of Mr. Epps (of Epps's cocoa), £735,837, Senator the Hon. G. T. Fulford of Canada (of Dr. Williams' Pink Pills) £1,311,000, Mr. Charles E. Fulford (of Bile Beans) £67,187, Mr. Benger (of Benger's Food) £420,807, Mr. Mellin (of Mellin's Food) £114,812, Mr. Owbridge (of Owbridge's Lung Tonic) £112,214, Mr. Handyside (of the "Consumption Cure") £147,860, Mr. Beecham (of Beecham's Pills) £86,680, and Mr. Commans (of Areca Nut Tooth Paste) £119,218. We do not think it fair to class these names together, for whereas some, whom readers will recognise, are those of gentlemen of responsibility and upright standards, some of the others have been scoundrels of the most heartless character. But, taking the fortunes left by them all, they cannot but suggest comparison with fortunes left by medical men. Sir Andrew Clark is the only medical man of the last fifteen years who has from his earnings left a sum approaching these figures, and his fortune was as nearly as possible that of the poorest of those mentioned above, namely, Mr. Beecham. The pessimist, looking on the exiguous earnings of medical men, will be inclined to ask, *Cui bono?*

Malvern Hydro Again.

The "Malvern Hydro" case has entered on a new phase. Whereas after a lengthy trial Dr. Fergusson eventually obtained a verdict of the jury in his favour, with £7,500 damages, last week the Court of Appeal reversed the judgment into one in favour of the Malvern Urban District Council. This decision is very unfortunate for Dr. Fergusson. It is clear that the jury sided with him, but, owing to misdirection of the Judge and other circumstances, the verdict was not upheld, and now we suppose the House of Lords will be appealed to. What the costs of this trial are already we can only conjecture, and even their present magnitude will be considerably added to by further appeal. It is events and issues of this kind which keep private persons from litigation; indeed, many lay to heart the advice of the late Mr. Commissioner Kerr, to bear any injustice rather than go to law. The strain on the finances of public bodies is severe enough; in the case of the Malvern Council it is known that a special rate will be necessary, but in the case of private individuals the amounts are ruinous.

LEADING ARTICLES.

OUT-PATIENTS AT GENERAL HOSPITALS.

The question of the relation of the out-patient hospital system to the general practitioner has been before the profession for many years. In spite of much discussion, however, it cannot be said that any material alterations have taken place. Signs are nevertheless to be seen on all sides that ere long efforts of a strenuous and comprehensive nature may be made to settle this vexed question upon a common-sense basis. The cry of the public is naturally for free and easy access to the benefits afforded by the medical charities. The complaint of the general practitioner is that he is robbed of a legitimate field of practice by the indiscriminate charity of the hospitals, and, above all, by their adoption of the "pay system." The medical charities themselves are engaged in a competition—apparently reckless—wherein success is measured by the revenue brought to their individual coffers and by the number of patients whom they relieve. Surely there should be some way of ascertaining where the truth lies amidst these conflicting interests, and in arriving at some grounds of reasonable readjustment. Probably one of the most important discussions upon this subject that has ever taken place was held last week in South London, on April 30th last, attended by some 150 medical men. The occasion arose out of a letter by Dr. Silk, Secretary of the Watching Committee of the King's College Hospital, asking the British Medical Association to inquire locally as to the best means of protecting the interests of practitioners in the conduct of the out-patient department to be built at Denmark Hill, and of the admission of in-patients, and to secure an expression of the views of the practitioner on the question of paying patients. It is hardly necessary to remind readers that King's College Hospital some years ago determined to shift from its central position to a densely-populated South London suburb. As a result of negotiations, a South London Hospital Committee was formed, and they passed resolutions which were approved by the King's College Committee, as follows:—"That there be no issue of subscribers' letters; that sickness and poverty be the qualification for hospital treatment; that no charge be made for the treatment of any patient of the hospital, or for the supply of medicine or dressings; that urgent cases receive attention without inquiry; that each application for treatment, on his first visit, be seen by a registered medical practitioner, and attended to; and that the name, age, address, occupation, or position be entered on a register." At the meeting of April 30th a resolution was moved strongly disapproving of paying patients in hospitals, and expressing a hope that King's College would not adopt that system. This was carried *nem. con.* The next resolution urged King's College to adopt the system of admitting patients only on certificates from medical practitioners. This was shelved by an amendment:—

> "That this meeting of South London registered medical practitioners understanding (1) that at the present time a Royal Commission is inquiring into the Poor-law system; (2) that the King Edward Fund has decided to inquire into the system prevailing at the large general hospitals of London with regard to the

admission of out-patients; and (3) that for the uses of the sick poor resident in Camberwell and district there are already provided 26 hospitals, 5 infirmaries, 18 dispensaries, and 9 other institutions; considers that there has been no evidence offered of the necessity for any out-patient department at the proposed King's College Hospital on the lines of those at the large London general hospitals; regrets that a contract for £65,000 for such a department has been placed; and is of opinion that a small out-patient department to which will be admitted either for consultation or treatment only those recommended as suitable by registered medical practitioners as suggested in resolutions 6, 7, 8, 9 and 11, would amply meet the needs of the district; would fulfil all requirements for the education of students, and should be given a fair trial.

"That the Lambeth, Norwood, and Wandsworth Divisions, the Metropolitan and South-Eastern Branch Councils, as well as the Central Council and Representative Body of the Association, be urged to approve and support this resolution, a copy of which shall also be sent to King Edward's Hospital Fund, the Hospital Saturday and Sunday Funds, the Charity Organisation Society, King's College Hospital Board, the *Lancet* and *Journal*, and the Press generally."

The resolutions referred to in the above are:—

(6) That, on a second application for treatment, a patient bring with him a recommendation signed by a qualified medical practitioner, stating that such patient is a suitable person for hospital treatment.

(7) That such certificate be written on a form supplied by the hospital.

(8) That such certificate, duly filled up, be appended to each patient's prescription paper or attendance card.

(9) That the following be submitted to the authorities of King's College Hospital as the ordinary form to be supplied to patients attending the hospital for the first time.

(Medical certificate appended.)

(Reverse side of certificate):—

In signing this certificate, the practitioner is requested to keep in view two points:—

(1) That the applicant is not in a position to pay for treatment;

(2) That the case is, from a hospital point of view, suitable for treatment.

(11) That it would be satisfactory if a system could be arranged whereby obscure and interesting cases might be brought or sent with a note by practitioners for an opinion when a consultation fee cannot be paid.

This amendment was adopted, with seven dissentients, and on being put as a substantive motion, was carried unanimously. Space forbids further comment here, but it seems sufficiently obvious that an enormously important precedent has been established, both in the recognition of the rights of general practitoners to have a say in a matter so closely affecting their interests in the establishment of a huge local out-patient department in their midst, and, further, the establishment of a general organisation of all members of the local profession for the purpose of presenting their views in clear and articulate form.

FLIES AND DISEASE.

One of the problems of the future will assuredly be how to deal with flies in relation to disease. For years past it has been repeatedly demonstrated that flies can, and do, act as agents in the distribution of pathogenic bacteria. The peculiar habits of these insects have long been recognised with regard to food and *habitat*, more especially as concerns the deposition of ova, and their ubiquitous invasion of dwelling-houses. At the same time, a great deal remains to be learnt in this particular matter before it can be regarded as having been brought within the range of practical sanitation. The appearance of a report dealing with the subject by so able an authority as Dr. Hamer, Assistant Medical Officer of the London County Council, is, therefore, particularly valuable. We are now on the threshold of summer, the season in which the flies breed and multiply. The inquiry originated in a complaint made in a certain Education Committee as to the use of a piece of land near one of the schools as a depôt for street sweepings. It was found that in this case a nuisance was undoubtedly caused by the breeding of innumerable flies and their diffusion among neighbouring dwellings. These observations were extended so as to include such premises as cow-houses, a knacker's yard, stables, manure depôts, and so on. Observation centres were established at distances of 50 and of 200 yards, and at these spots flies were caught on pieces of paper smeared with honey-gum. The conclusions are definite enough on the point that the most productive centre for flies is in collections of horse manure, but that all other dust and refuse heaps act in a similar but minor degree. Their influence is felt inversely to distances up to 200 yards and more. Local difference of condition in individual houses determine the extent of their visitation by flies. Thus, rooms with dirty walls and ceilings, or where crumbs are scattered about and act as food, the presence of children, warmth, nearness to ground floor, open windows, are all favourable factors. Dr. Hamer draws no definite conclusions as to the relationship of flies to epidemic diarrhœa, on the ground of insufficient data. It is true that the flies and the disease increase together and attain their maximum about the same time, but the curve of the disease falls while the number of flies still remains excessive. Dr. Hamer remarks that, "on the whole, while it is not easy to reconcile the behaviour of the curves with an hypothesis that flies transmit diarrhœa, it must be admitted that the phenomena accord quite well with the supposition that both flies and diarrhœa stand in close relation with temperature." Sir Shirley Murphy, who presented the report, remarks aptly that, even in the absence of direct proof of disease-dissemination, the well-known habits of flies compel us to regard them with disfavour. We could go further than that and say that, in the light of numerous experiments and observations, it is impossible to doubt that flies in some cases convey disease directly or indirectly to man. In any event, the practical lesson in prevention is that no accumulations of filth or refuse of any kind should be permitted in towns or near houses in the country, and that flies should as far as possible be excluded from our dwellings.

CURRENT TOPICS.

The Apotheosis of the Spectacle maker.

When Charles I. granted a royal charter to the Worshipful Company of Spectaclemakers, in 1629, that body represented a well-defined craft. As a matter of fact, the science of ophthalmology, more especially that part dealing with errors of refraction, was as yet unborn. By degrees an accurate knowledge of visual optics and of the physiology and pathology of the complex structures and phenomena concerned, has been gradually evolved by the labours of medical men. There is probably no branch of medicine which more nearly approaches the level of an exact science than that of the ophthalmic surgeon, and no study that demands greater special aptitude and assiduous study. Yet the spectaclemakers have claimed the right to follow on the heels of the scientific ophthalmologist, and to be experts not only in the making of good spectacles, but also in the many abstruse fields of study with which the ophthalmic surgeon must be familiar. From a recently-published syllabus, it may be gathered that the Company hold three examinations. The first is a preliminary devoted to mathematics (including trigonometry), and to general optics, including the use of the ophthalmoscope, perimeter, chromometer, making of lenses—in short, a general survey of ophthalmic practice. In the final examinations the candidate has to show a knowledge of various instruments, such as the microscope and barometer, and a number of scientific points necessary to the scientific understanding of the human eye, which we should have thought absolutely unnecessary for the man who is to make our lenses and fit our frames. The Worshipful Company, however, is not content until it has imposed a high standard test which would strain the capabilities of many a well-trained medical man to satisfy, even after a long course of special study and experience. The subjects set forth are: "Static and dynamic refraction of the eye. Accommodation and convergence. The movements of the eyeball and muscles employed. The near and far points. The range and amplitude of accommodation and convergence. The course of light through the media of the eye alone and modified by spherical and cylindrical lenses and prisms. Emmetropia, hypermetropia, myopia, astigmatism, amisometropia, aphakia, presbyopia, asthenopia, amblyopia, orthophoria, heterophoria, strabismus, diplopia, the fields of vision and fixation, stereoscopy. Chromatism of the eyes—tests for the same—colour vision and blindness." We venture to assume that any spectaclemaker who mastered the foregoing—supposing that were possible for a man without careful medical training—would have little time to devote to his lenses. It would be no less absurd to demand of the ophthalmic surgeon a knowledge of the theory and practice of making spectacles. One of the most curious features of the whole farce is the presence of a member of the Ophthalmological Society upon the board of examiners. If the Society be content, who can differ?

Midwives in Chicago.

DURING the past year an important investigation into the training and conduct of the midwives of Chicago has been carried out by the Chicago Medical Society. In Chicago some 47 per cent. of the births are conducted by midwives, the highest proportions being among the Italian, Slav, and German communities. In the investigation particular attention was paid to the question as to whether the midwife was engaged in criminal practice or not. Of 223 licensed midwives, no less than 49 responded to the suggestions of the detective by promising to perform illegal operations! 41 others were regarded as giving rise to suspicion. It appears that whereas midwives must obtain a licence from the State Board of Illinois in order to practice in Chicago, yet once they have received their licences they are under no further control. Of course, the practice of abortion is in the United States, as in most other countries, a crime, yet it is treated with greater laxity there than elsewhere. Lombroso, years ago, referred to this toleration of abortion in America, stating that abortion was generally regarded as a perfectly justifiable, even laudable, method of limiting a family. The general education and fitness of the women for their duties was very unsatisfactory, many of them being dirty in the extreme. It is interesting to note that the highest efficiency was found among women trained in European schools and maternities. We are accustomed to grumble at the conditions of practice by midwives in these countries, but, at any rate, they have not reached the level of Chicago.

Asleep at his Post.

THE theory which has been put forward by Colonel Yorke, the Board of Trade Inspector, to account for the recent accident at Shrewsbury, has caused, naturally enough, a considerabie sensation among the travelling public. The suggestion is that the engine-driver was asleep at his post. There is, of course, in this particular case, little to support the theory as a positive explanation beyond the absence of any other explanation, and the fact that the driver had been on duty the previous night. However, if we are to believe Professor James and the Pragmatists, any explanation is true till a better is found, and so in the absence of another we may admit the truth of Colonel Yorke's hypothesis. Judged in the abstract, indeed, there is nothing improbable in it, for even in such a position as on the footplate of an engine a man may for a moment be overcome with sleep, and that moment may happen to be the critical one. Many of us can recall sleep suddenly overpowering us even during moments of fixed attention, the sleep, perhaps, only lasting for a few seconds, and being unnoticed by others. For instance, on horseback, or even in teaching a class, one recalls lapses into unconsciousness of probably a few seconds' duration. To a man accustomed to the somewhat monotonous work of driving an engine there is nothing to prevent a sudden lapse of the sort. The practical lesson to be learnt is that greater precautions are necessary to prevent the possibility of railway servants, while suffering from severe fatigue, being permitted to undertake duties of great responsibility.

Arsenite of Copper Poisoning.

OF late years a vast amelioration has taken place in the condition of workmen engaged in "dangerous" trades. That there is room for improvement, however, is unfortunately only too obvious, in spite of the unwearied efforts of the Home Office and its inspectors. A coroner's inquiry into the death of a man engaged in some colour works points to an unfortunate laxity somewhere along the line of prevention. Deceased had been engaged in grinding colours for one firm during the past six years, and for some weeks had been working overtime on green paint, otherwise arsenite of copper. The verdict of the jury was that deceased "died from coma and convulsions, and gastro-enteritis, set up by his work with arsenite of copper." It appears that some time before he was compelled to leave off work he complained of a sore on the foot and of his nose being affected. It seems pretty clear that under any efficient system of supervision a man working on so dangerous a material would have been promptly suspended from his occupation. The situation becomes more than ever inexplicable after the admission of the foreman of the works that ten or twelve men had been invalided since Christmas last through working on the same stuff. No doubt the circumstances will receive due attention at the hands of the Home Office.

The New Fellows of the London College of Physicians.

Some time ago we felt it our duty to criticise somewhat adversely the methods, or what appeared to be the methods, of the Royal College of Physicians of London in the allotting of their Fellowships. It was pointed out that this purely honorary distinction was in many instances conferred upon comparatively young or little known men having strong College influence, to the exclusion of members of recognised standing in the provinces. We are glad to note that a fresh policy appears to have prevailed in the councils of the College, if we may judge from the recently announced list of Fellows. The names are:—

> The following members were elected as Fellows of the College: Robert Charles Brown, M.B. Lond.; George Ogilvie, M.B. Edin.; Charles Henry Cattle, M.D., Lond.; John Elliott, M.D. Lond.; Guthrie Rankin, M.D. Glasg.; Theodore Fisher, M.D. Lond.; Robert James McLean Buchanan, M.D. Vict.; Arthur Francis Stabb, M.B. Camb.; William Henry Butter Stoddart, M.D. Lond.; Arthur Latham Ormerod, M.D. Oxon; Walter Langdon Brown, M.D. Cantab.; Alfred Ernest Russell, M.D. Lond.; Reginald Cecil Bligh Wall, M.D. Oxon; Thomas Wardrop Griffith, M.D. Aberd.; and Leonard Stanley Dudgeon.

The College is to be congratulated on this change of policy, which can hardly fail to stimulate a somewhat flagging interest. The existence of a purely honorary diploma, conferred without examination, constitutes a curious anachronism which it would be hard to defend seriously when the whole question of medical qualification is brought under the searchlight of public inquiry, as must one day happen.

PERSONAL.

The King of Norway has conferred the Grand Cross of the Order of St. Olav on Sir Francis Laking.

Lieutenant Colonel Falvey, R.A.M.C. (retired) has been placed on the Commission of the Peace for County Donegal.

Dr. Egeberg, Physician in Ordinary to the King of Norway, has been created a Commander of the Royal Victorian Order.

Dr. A. J. Laird, late medical officer for Crewe, has been appointed medical officer for Cambridge, at a commencing salary of £500 a year.

Dr. Ian Macdonald, who resides in Spain, has been elected a corresponding member of the exclusive Société de Pathologie Exotique of Paris.

Private C. W. Wirgman, of the London Scottish, who won a first prize in the competition for the *Daily Telegraph* Cup, is a medical man in practice as an ophthalmic surgeon.

The Edmonton Education Committee has appointed Dr. F. E. Rock, assistant medical officer of health at Huddersfield, as medical inspector of schools, at a commencing salary of £250 a year.

The salary of Dr. Bostock Hill, of Birmingham, has been increased by £250 a year in respect to his duties in connection with the medical inspection of school children.

Dr. T. W. H. Garstang will open a discussion on the "Inspection of Dairies and Cowsheds" at a provisional sessional meeting of the Royal Sanitary Institute to be held at Shrewsbury on Saturday, May 23rd.

Dr. Meredith Young has been the recipient of no less than five presentations from colleagues at Stockport, on leaving that town to take up his new duties as Medical Officer of Health of Marylebone.

Dr. B. W. Housman has been presented with a handsome rose-bowl and other gifts by his colleagues of the Stockport and District Medical Society and the local Division of the British Medical Association on leaving the district.

A number of persons connected with the Hertford General Infirmary have presented Dr. J. T. Trasker-Evans with a handsome tea and coffee service and a cheque for £42 on his resignation after 29 years' active work at that institution.

Mr. Watson Cheyne, C.B., F.R.C.S., will deliver the Wightman Lecture before the Society for the Study of Disease in Children on Friday, the 22nd inst.; his subject will be "The Defensive Arrangements of the Body as illustrated by the Incidence of Disease in Children."

Lord Cheylesmore has received from an anonymous donor, through Mr. William Hern, dental surgeon to the Middlesex Hospital, the sum of £500 in response to his recent appeal on behalf of the fund for the maintenance of the Cancer Investigation Department of the hospital.

Professor David W. Finlay, M.D., LL.D., F.R.C.P., will take the chair at the dinner of the Glasgow University Club at the Trocadero on Friday, May 29th. The hon. secretary of the club is Mr. Craig Henderson, of 2, Paper Buildings, Temple, E.C.

Sir Frederick Treves, Bart., has promised to take the chair at the jubilee dinner of the Royal Dental Hospital, Leicester Square, to be held next month at the Hotel Cecil. The debt of £47,404 on the building weighs heavily on this institution, and Sir Frederick is making a public appeal on its behalf.

The will of Dr. Henry R. Silvester, author of the Silvester method of resuscitating the apparently drowned, has been proved at £25,415. The deceased was on the committee of the Royal Humane Society, in which he took an absorbing interest.

A series of lectures under the auspices of the Women's National Health Association was inaugurated on May 6th by her Excellency the Countess of Aberdeen in Dublin. There was a large attendance. His Excellency the Lord Lieutenant presided. Their Excellencies were accompanied by Captain Coates, A.D.C., and Sir W. J. Thompson, M.D.

Dr. A. W. Martin, the medical officer of health for Gorton for 21 years, has issued his yearly report to the District Council, and this will be his last, seeing that the district becomes a part of Manchester in November.

The Council of the Manchester University having decided on the appointment of a second Professor in the Department of Medicine, one of the Chairs will be devoted to Clinical Medicine and the other to Systematic Medicine. Dr. Graham Steell, now Professor of Medicine in the University and Senior Physician in the Royal Infirmary, will hold the Chair of Clinical Medicine.

Dr. George R. Murray, who till recently held the Heath Professorship of Comparative Pathology in the Durham University, has been appointed Professor of Systematic Medicine. Under the agreement entered into between the University and the Royal Infirmary, Dr. Murray becomes on his appointment a member of the honorary staff of the Royal Infirmary.

A CLINICAL LECTURE
ON
EARLY DIAGNOSIS IN SURGICAL DISEASES OF THE KIDNEY, WITH SPECIAL REFERENCE TO PHYSICAL METHODS OF EXAMINATION.

By **DAVID NEWMAN, M.D., F.F.P.S.G.,**
Surgeon, Royal Infirmary, Glasgow.

(Concluded from page 498.)

4.—Cystoscopy.

The objects in view in making a cystoscopic examination in renal cases are:—

(1) To eliminate lesions of the bladder from the diagnosis.

(2) To reveal the presence of any foreign body, calculus, plug of muco-pus or blood-clot impacted in the mouth of the ureter.

(3) To compare the appearance of the ureteral orifices.

(4) To observe the size, character and frequency of the urinary shoots from each ureter.

(5) To detect the absence of a ureter orifice on one side, or of a flow of urine from one ureter only.

The following observations have a very direct bearing upon cases where important questions require to be answered very definitely and clearly when operative interference is contemplated.

In a case where the evidence points to a renal lesion, but neither the symptoms nor the physical signs clearly indicate the organ involved (for example, hæmaturia from a small tumour in the kidney), the cystoscope will show the side from which the blood is escaping. When there is a doubt whether the disease is limited to the kidney or also involves the lower urinary organs (tuberculosis), the cystoscope will show the extent of the lesion in the bladder. In some cases of renal calculus the pain is referred by the patient, not to the kidney containing the stone, but to the position occupied by its healthy neighbour (reno-reflex pain). When hæmaturia is present, blood will be seen escaping from the ureter corresponding to the kidney containing the calculus, and when there is no bleeding, an irritable condition of the lips of the ureter will betray the site of the disease.

One kidney is known to be diseased. Is the other functionally active and fit to do double duty when called upon? By watching the character, size, and frequency of the shoots from each ureter, a very clear idea can be arrived at as to the activity of each kidney.

The majority of surgeons recognise the use of the cystoscope in its application to vesical disease, even although they may not practise its use; but few fully appreciate its value in gaining information regarding renal lesions. It should be a routine practice to make an examination of the bladder of all renal cases prior to operation, almost as regularly as examination of the urine. By so doing many fallacies in diagnosis and errors in treatment will be avoided.

In relationship to diseases of the kidney, examination of the bladder with the cystoscope has proved of great practical value, not only in a negative way by eliminating lesions of the bladder from the diagnosis, but also by giving positive evidence of the presence of disease in one or both kidneys. When nephrectomy is contemplated on one kidney, a knowledge of the presence and functional activity of the other is of primary importance. From ocular inspection, if carefully carried out by an educated eye, exact conclusions may be drawn which cannot be arrived at by other means, and the course of treatment can be decided upon early in the course of the disease. By so employing this method, most valuable time may be utilised, which would otherwise be wasted, waiting for other evidence to prove the nature of the renal lesion. Too often, when we wait until the symptoms are sufficiently significant to form a basis for diagnosis, the disease has advanced beyond our power to remedy.

Cystoscopy, when conducted with aseptic precautions, is unattended with danger, and is comparatively easily carried out in both sexes, but, for obvious reasons, with greater facility in the female.

Prior to a cystoscopic examination, careful inquiry should be made into all the circumstances of the patient. In those suffering from serious disease, and in whom the introduction of an instrument is likely to be followed by aggravation of the symptoms, cystoscopy should not be resorted to unless the patient is prepared to submit to an immediate operation, should it be deemed necessary.

In health the urine collects slowly above the closed sphincters at the orifices of the ureters, and at intervals is thrown by squirts with considerable force into the bladder. The length of the intro-missions depends upon the activity of the kidney. Under favourable circumstances, about 10 to 15 drops are ejected alternately from each ureter every 30 or 40 seconds. By carefully watching the line of the ureter, the portion coursing through the wall of the bladder, the part immediately above the sphincter, will be seen gradually to distend.

Immediately before the urinary squirt appears, the expanded duct, looking in form not unlike a miniature engorged leech, is drawn slowly upwards and outwards. It gives a sudden wriggle, its muscular fibres contract, the sphincter is forced open, and the contents are ejected. The urine, as it is thrown into the bladder, forms a distinct jet which shoots downwards and inwards. The spurt occupies about two seconds. The form of the spout can be seen most easily in cases of renal hæmaturia. The aspect of the orifices of the ureters individually, and in relation to each other, is important to observe. It may be stated as a general observation that when the appearance of the orifice of one ureter is altered, while that of the other is normal, the renal lesion is on the side of the morbid ureter. And, again, if the number of urinary shoots be counted within a given time, as they occur from each side, and a marked difference is observed, the side on which most shoots are seen is either the site of considerable local irritation or is the most active organ functionally. When due to morbid irritation, the shoots not only succeed one another rapidly, but they are of short duration, and the urine which escapes is small in quantity; whereas in increased functional activity the shoots, in addition to being frequent, are prolonged, and the amount of the urine is large. Instead of coming in regular and distinct jets every 20 or 30 seconds, the force of the shoots may be diminished. The manner in which the urine enters the bladder may be so slow as to be hardly perceptible. In stricture of the ureter, or when its lumen is obstructed by a stone, the urine may dribble into the bladder, just as it dribbles out of it in enlarged prostate or in stricture of the urethra. In describing the orifices of the ureters we may speak of the inner and outer lips, and the upper and lower angles. In many cases the orifice of a ureter may not be visible, but it is not necessarily to be concluded that the orifice is absent or displaced; it may be merely hidden—at one examination easily seen, at another not to be found.

In some cases certain facts can be ascertained regarding surgical renal lesions by an examination with the cystoscope. For example, in many cases of renal hæmaturia, and in some cases of pyuria, the escape of blood or of pus from a ureter can be readily seen by the cystoscope. When the amount of blood present is small, but still sufficient to perceptibly stain the urine, the cystoscope is, in the male, more reliable than the ureter catheter, the introduction of which into the inflamed ureter may cause a little bleeding and so vitiate the value of the observation. Pus may escape in different ways, according to the consistency of the fluid In many cases the quantity of pus discharged from the kidneys is small, and its escape so irregular that the cystoscope fails to establish from which kidney the purulent urine flows. When, however, the diseased kidney is secreting little urine, and the quantity of pus is considerable, the discharge may be readily seen escaping from the ureteral orifice. In some instances it is forced out of the ureter in form and appearance not unlike a cheese maggot, and little masses of purulent discharge may be seen on the floor of the bladder curled up like dead maggots, unmixed with the solution introduced for the cystoscopic examination, but when the bladder contracts to expel its contents, the force required to drive them out causes the purulent masses to lose their form and become intimately mixed with the fluid. In this way they are deprived of their characteristic form, which can be observed only while they are within the bladder. The appearance of more or less slight effluxes indicates that the kidney from which they come has ceased to be functionally active. On the other hand, when the pus is seen to escape in distinct shoots, the kidney may be presumed to be still secreting a considerable quantity of urine.

From what has been said, it will be seen that many of the objects aimed at by using ureter catheterisation may be obtained more easily and with greater safety by skilful use of the cystoscope.

Cystoscopic diagnosis of renal disease may be summarised in the following conclusions:—

(1) When one ureteral orifice is altered, while the other is normal, the renal lesion is on the side of the morbid ureter.

(2) When the urinary shoots are more frequent on one side than on the other—(*a*) greater functional activity is indicated by the shoots being uniform in size and regular in rhythm; (*b*) undue irritation of the kidneys is to be inferred when the shoots, while more frequent than normal, are irregular in rhythm, unequal, and small in size; (*c*) stricture, stone or chronic ureteritis should be suspected when the shoots are distorted in form or irregular in amount.

(3) When the urine does not escape in distinct jets —(*a*) dilatation of the ureter without paralysis of the sphincter is indicated when the urine dribbles into the bladder at intervals; (*b*) destruction of the sphincter action is shown by the urine flowing into the bladder almost continually.

(4) The character of the morbid fluids escaping from the ureter, or of clots, etc., occupying the opening, denotes the morbid changes taking place in the corresponding kidney.

(5) The deformity of the orifice also indicates the character of the renal disease—(*a*) pin-head contraction (chronic inflammation or impacted calculus); (*b*) elongated and distorted (distension of renal pelvis or infected nephritis); (*c*) swollen or pouting (prolonged but not acute inflammation or renal parenchyma); (*d*) dilated (advanced tuberculous or calculous pyonephrosis); (*e*) U-shaped (significance doubtful—usually denotes prolonged irritation of renal pelvis).

5.—THE METHYLENE BLUE TEST

is of value not only in enabling the observer to more readily see the urinary shoots, but also in testing the functional activity of the excreting organs.

The relative functional activity of the two kidneys can most easily be ascertained by employing the cystoscope. When methylene blue is administered by subcutaneous injection of 1 c.m. of a 5 per cent. sterilised solution of methylene blue, the blue colour should first appear in the urine about an hour thereafter, and increase in depth for about six hours, and then, gradually diminishing in intensity, disappear entirely within 40 to 42 hours. When the kidneys are diseased the colour takes a longer time to appear, the colouration is not so intense, but lasts much longer. Elimination is delayed. This may apply to one or both kidneys. A healthy, active kidney eliminates the blue rapidly and in large quantities, whereas a defective or diseased organ excretes it in small quantities or not at all, chromogen alone escaping, the presence of which may be detected by boiling the urine, after acidulating with acetic acid. By comparing the colour of the shoots from each ureter, say, three hours after the injection has been given, an estimate of the functional activity of each kidney may be obtained.

6.—RADIOSCOPY.

The service rendered to the surgeon, not only in detecting the presence of a stone, but also in locating the concretion in the kidney or ureter by the employment of Röntgen rays, is too well-known to require remark. At first the results were disappointing, but now improved methods of working, together with larger experience in interpreting what is seen through the fluorescent screen, enables correct conclusions to be arrived at.

Many substances opaque to ordinary light, such as wood, cardboard, cloth, and the soft tissues of the body, are translucent to these rays, but while the rays pass through such substances, to the unaided eye they do not affect the sense of vision, although they at once act upon the ordinary photographic plate, and they produce fluorescence in certain substances, such as the platino-cyanides. In searching for renal calculus, we take advantage both of the photographic plate and the fluorescent screen. These methods have the advantage that they not only demonstrate the presence of stones, but they also afford valuable information as regards their number, position, shape and size. All matter is transparent to X-rays, and, roughly speaking, the penetration is in inverse ratio to the density of the substances. Dense, heavy materials, such as lead and silver, are almost impenetrable, while aluminium is translucent. Bone is opaque compared with soft tissues, but transparent as compared with a stone or metallic substance. So it is with renal calculi. Some are more opaque to the rays than others. We find that those composed of oxalate of lime give the deepest shadow, uric acid the faintest, while the shadow of phosphatic stones occupies an intermediate position. Hence the chemical composition of the stone, and the greater or lesser opacity associated with it, are most important factors, upon which the success or failure of the skiagraph depends. By improvements in apparatus and in *technique*, now even uric acid calculi can usually be detected by the fluorescent screen, which is more accurate in the hands of the skilled observer than the skiagraph. The skiagraph, however, has the great advantage of being a permanent record, while the other is literally a fleeting shadow. There are many dangers of obtaining false shadows which are liable to be mistaken for those of stone, and we must admit that the difficulties of obtaining a shadow of calculi *in situ* in the kidney or ureter are due to many causes. It is by recognising these difficulties that we have practically overcome them, and steadily the percentage of our failures is becoming less.

In each individual case the tension of the rays and the length of exposure must be carefully considered, and before the shadow photograph is taken, or, better still, while it is being taken, the penetrating power of the rays must be observed through the fluorescent screen. Before taking a photograph of the shadow, it should be carefully located by the fluorescent screen and its position marked by crossed wires which come out in the radiograph. The wire can then be removed and the relation of the stone to the cutaneous surface fixed by markings with nitrate of silver.

Errors in diagnosis may be considered in two divisions—those in which a shadow is discovered and believed to be due to stone, but the surgeon fails to find it, and those in which the stone is removed by the surgeon, but no shadow betrays its presence. The most common cause of false shadows is the presence in the abdomen or its walls of substances with a high absorptive index, such as fæcal matter, fruit stones, the presence of bismuth salts, enlarged and calcified glands, old purulent accumulations, cicatrices and phlebolites.

The most common and characteristic position for a stone is in the angular space formed by the eleventh rib and the spinal column. Very often the shadow of the stone is covered by the last rib. A clearly defined shadow in this position is almost certainly due to calculus, but it must also be borne in mind that tuberculous material may give a shadow. The margins of the shadow, however, are indistinct, although the central portion may be as deep as that given by a stone. It is when shadows are found in other regions that doubt arises. Those due to calculous matter may, of course, be found in any part of the urinary tract, and the more closely the situation of the shadow corresponds to the anatomical position of the pelvis of the kidney and the ureter, the greater the suspicion of stone.

It is, therefore, useful in doubtful cases to pass a metal catheter into the ureter, and photograph it along with the stone But, on the other hand, a shadow well outside the line of the ureter may be caused by a stone, although this is a rare occurrence.

NOTE.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Robert A. Fleming, M.A., M.D., F.R.C.P.Ed., Physician to the Edinburgh Royal Infirmary, Lecturer on the Principles and Practice of Medicine in the Edinburgh Medical School, Examiner in Medicine, Aberdeen University. Subject: "Sciatica."***

ORIGINAL PAPERS.

FOUL BREATH: ITS CAUSES, PATHOLOGY AND TREATMENT. (*a*)

By ANDREW WYLIE, M.D.,

Assistant Surgeon, Central London Throat and Ear Hospital.

MR. PRESIDENT AND GENTLEMEN,—Having received the honour of an invitation to read a short paper, it has occurred to me that some remarks on the subject of foul breath might possibly interest the members of this Society.

I hardly dare lecture on any disease connected with the throat or ear in the presence of our President, more especially after his able address before this Society at the beginning of the session. The subject of foul breath, however, although closely allied to the work of the laryngologist and rhinologist, is also one which closely concerns many other forms of practice.

Foul breath is such a source of annoyance to the individual, such a discomfort to friends, acquaintances and fellow-workers, that to be able to treat it, not only temporarily, but to get rid of it altogether, you will confer, not only a boon on your patients and your fellow-men, but you will also earn their gratitude.

Twenty minutes is a short time in which to discuss this important subject, and the fringe of it can only be touched. Arising, as this symptom does, from many different causes, I propose briefly to consider these, and to indicate the treatment appropriate to the several conditions.

Fœtor of the breath may be either purely subjective or entirely objective, or the odour may annoy both the patient himself and those with whom he is brought into contact.

When subjective it is, of course, experienced by the patient alone. Examples are met with in the peculiar sensations of smell experienced by patients suffering from perityphlitis, chronic constipation, obstruction of the bowels, liver abscess, malignant disease of the intestinal canal. Of the same order also is the "curious burning smell" noticed by patients suffering with disease of the brain and associated with abscess or tumour in the vicinity of the temporo-sphenoidal lobe. (*b*)

Objective fœtor is observed by persons associated with the patient. In most instances the patient is himself also conscious of the odour. This is due to many causes which we may now discuss.

There are different types of fœtor.

(1) The putrefactive type is the commonest. Its odour is like decomposing cheese. It occurs in such diseases as that form of rhinitis in which the pus has become hard and cheesy, a condition associated usually with disease of the antrum, and called caseous rhinitis. A similar odour is found also when decomposing material collects in the naso-pharynx, pyriform fossæ and tonsil crypts, and in tertiary specific disease of the nose and pharynx.

(2) The sulphuretted hydrogen type, which we all know from old association with chemical laboratories, is peculiarly obnoxious, and for this reason it is a favourite implement of warfare at political meetings. It occurs in gangrene of the lung, in bronchiectasis, etc., and it is often so pungent as to cause the friends and even the nurse to avoid the sufferer.

(3) The garlic type, which every traveller knows who has visited Spanish or Italian countries, or who has associated with individuals who eat onions. This odour is also apparent in those who take such drugs as bismuth and arsenic regularly. Ladies who take arsenic for cosmetic purposes should be warned of its deleterious effect.

(4) The sweetish type is one of the diagnostic signs of glycosuria, and is generally associated with the presence of yeasts, etc., in the throat and nose; also in beer drinkers.

(5) The toxic or hepatic type is associated with various forms of bacteria, such as the bacillus butyricus, which is found in the mouth, nose and fauces of dyspeptic "bilious" people and also in those who do not properly masticate but "bolt" their food in an irrational manner, or in those who do not clean their teeth.

Fœtor of the breath may further be classified according to the different regions which are responsible for its source. These are the mouth, nose, naso-pharynx, larynx, and lungs. Fœtor is also due to general constitutional disturbances.

The common causes of foul breath may thus be briefly summarised:—

(1) Diseases of the nose and its accessory cavities, causing nasal obstruction and mouth breathing.
(2) Imperfect deglutition.
(3) Oral and lingual affections.
(4) Diseases of the teeth and gums.
(5) Diseases of the tonsils.
(6) Chronic suppuration of the middle ear.
(7) Affections of the naso-pharynx.
(8) Diseases of the lung.
(9) Foreign bodies in the mouth, nose, pharynx or larynx.
(10) Constitutional causes.

Nasal obstruction, or mouth breathing, may be due to adenoid growths, enlargement of the turbinal bodies, deviations of the septum, and spurs or outgrowths on the septum. All these cause not only imperfect ventilation through the nose, and the collection of more or less putrid secretion, but they also give rise to mouth breathing, perverted secretion, and dryness of that region.

Some diseases of the nose cause a specially pronounced odour—for example, rhinitis sicca, which arises when the secretion is impaired or diminished in quantity and quality. A similar condition is found in atrophic rhinitis, where actual structural degeneration of the mucous membrane has taken place; in caseous rhinitis, where the pus and *débris* are charged with various forms of moulds, yeasts, and putrefactive bacteria, such as *Aspergilli torulæ* and the *Bacillus butyricus*. In chronic diseases of the accessory cavities where pus is lodged in the maxillary antrum, or the ethmoidal, frontal, or sphenoidal sinuses, and in tertiary syphilis with necrosis of the ethmoid or vomer. In septal perforations, whether from operations, from tuberculosis or syphilis, there is also fœtor, and the same is found when polypi and sinusitis co-exist. Generally speaking, fœtor may be present in any malformation of the nose which interferes with free discharge and proper ventilation.

Another disease attended with fœtor is chronic epistaxis, especially the "leaky" form, which is occasionally found in plethoric individuals and in those suffer-

ing from portal obstruction, also in dysmenorrhœa. This form of epistaxis also occurs in cases where fibroma or sarcoma are present. The blood adheres to the mucous membranes, soon becomes septic, and so creates an unpleasant odour.

Before dismissing nasal disease as a cause of foul breath, I wish to mention a form of nasal obstruction common in adolescents which is not a real obstruction. The patient experiences the sensation of blocking. This condition arises from desiccation of the mucous membrane in roomy or wide nostrils, whereby its sensitiveness is lost, and the friction of the air current cannot be felt. It may be the result of a too energetic treatment of the turbinals by the galvano-cautery, or it may be due to constitutional causes, such as anæmia; it also arises from neglected infantile snuffles, or there may be an unusually patent channel. In all these conditions there is deficient secretion or exudation, and in this way there is afforded full opportunity for bacterial growth.

Imperfect deglutition causes accumulation of food in the mouth, round the teeth, in the buccal pouch, the tonsils, behind the soft palate, in the pyriform fossæ of the larynx, and in the glosso-epiglottic and hyo-epiglottic fossæ. Such conditions generally arise from paralysis of the muscles, especially that form which follows diphtheria or any of the fevers. It may also occur from habitual carelessness in swallowing. Some people do not completely empty the mouth before refilling it, and are very inattentive to oral hygiene. In all these instances the retained food undergoes decomposition, and the fœtor so produced contaminates the breath.

Oral causes of fœtor should be divided into two great classes—viz., those connected with the tongue and those connected with the teeth.

As regards the lingual causes, first may be mentioned a furred tongue. This may be merely a local manifestation of disturbed digestive functions, or it may be a local trouble by itself. There are several varieties of furred tongue.

(1) The hypertrophied condition of the papillæ seen in "black tongue" is a pigmentary deposit in elongated papillæ which are undergoing keratinoid degeneration. The cause of this condition is not known.

(2) The conditions in which accumulations of bacteria, such as yeasts, proteus vulgaris leptothrix, etc., congregate on the tongue.

(3) The state in which a superficial thickening of the epithelium has taken place, and which varies very much in character. When this condition is pronounced we have what is called leukoplakia, recognised by Fournier, Butlin, and others as frequently precancerous.

There are also:—

Ulceration of the tongue, which may simply be due to the irritation of a tooth or a symptom of digestive disturbance; when deep ulceration is present, is most likely due to the breaking down of a malignant growth or to tubercle or syphilis. The diagnosis in some cases is difficult, but as a rule tubercular ulceration of the tongue is shallow and not deeply excavated. It has well-defined edges and occurs without much pain, while specific and malignant ulcerations are generally painful. Histological examination of the scraping from these ulcerations will settle the diagnosis. (*a*)

As regards the dental causes, we have:—

(1) *Pyorrhœa alveolaris* (Rigg's disease), which may be acute or chronic, and often exists without actual disease of the teeth, being generally referred to as "spongy gums."

Tartar, and, later on, pus is formed and collects between the gum and the tooth, and little pockets result which lead to recession of the gum. The roots of the tooth are exposed, and the affection may result in caries. Administration of mercury often causes this condition. Pyorrhœa is associated with various bacteria, of which *Spirochæta refringens* and *B. fusiformis* are the most prominent.

(2) Decomposing food, tartar or pus between the teeth and at the seat of caries.

(3) Caries of the teeth and retained stumps.

(4) Imperfect and cheap artificial dentures and neglected hygiene.

As regards the tonsils:—

(1) The most common cause for tonsillar fœtor is a change which takes place in the lacunæ or follicles. These become filled with pearly masses of dead epithelial *débris*, and loaded with bacteria or particles of decomposing foods. Such lacunar accumulations can be expelled by pressure, and are thus distinguished from a keratosis which is closely adherent; in this latter also there is not necessarily any odour.

(2) Acute ulceration of the tonsils is not associated with any definite type of fœtor; it is in the more chronic forms where the odour is so unpleasant.

(3) Malignant growths and tertiary syphilitic disease of the tonsil itself do not cause fœtor at first, but these diseases soon invade the surrounding structures, which interferes with deglutition and favours bacterial activity; the fœtor then becomes pronounced.

As regards chronic suppuration of the middle ear, this often causes a fœtid breath by the stinking pus getting into the naso-pharynx through the Eustachian tube, and keeping the naso-pharynx (which in healthy states is sterile) in a septic condition.

Affections such as adenoid growths, simple and malignant neoplasms in the naso-pharynx, cause a fœtid breath by interfering with the proper movement of the parts, by accumulations of secretions and by obstructing the natural ventilation and drainage.

In the lungs putrefactive changes take place in such diseases as bronchiectasis and pulmonary gangrene, causing a most pungent and offensive odour. The smell of bronchiectasis is a mixture of sweetness and stink.

Foreign bodies in the nose, pharynx and larynx cause a most offensive odour, since they obstruct ventilation and drainage and excite inflammatory processes and sepsis. A familiar cause is that of foreign bodies, chiefly fish and splinters of meat bone, becoming embedded in the tonsil or pharynx. Pieces of shells, buttons, beads, plum stones, etc., in the nose cause discharges, crusts and odours; especially is this true if foreign bodies are allowed to remain and become encrusted so as to form rhinoliths. Foreign bodies in the larynx also cause a most offensive odour; typical examples of false teeth in the larynx are described in several text-books, and some years ago, in my own practice, a gentleman, after having several teeth extracted, experienced for three months a peculiar offensive smell, until one morning during a paroxysm of coughing, some pus and a stump of a tooth were expelled.

The last series of causes which I will enumerate are the constitutional ones, and under this heading I place:—

(1) Gastro-intestinal derangements and dyspepsia, especially those which are associated with dilatation of the stomach.

In patients troubled with severe chronic constipation there is a peculiar sickly, almost fæcal odour from the breath.

Spirit drinkers have quite a different odour from beer drinkers; the former is of a vinegar type, while the latter have the characteristic smell of stale malt liquor.

The breath of cigar and pipe smokers has a different smell according to the favourite form of using tobacco.

(2) Different varieties of glycosuria cause a sweetish odour to the breath.

(3) Menstruation always causes some change in the breath; in some individuals it is so pronounced that they can hardly mix with society during that period.

(4) During lactation also in some patients there is a marked odour from the breath.

(5) Drugs have a great influence on the breath, and it is one of the signs to watch for in their administration. Bismuth and arsenic have been already referred to. Lead and mercury produce a well-known effect on the gums, and in extreme cases much fœtor. All preparations of sulphur cause a characteristic sulphuretted hydrogen smell of the breath. Copaiba and valerian have a cats'-meat smell; iodoform a

---

(*a*) See case reported by Author, Medical Press and Circular, December 12th, 1906.

rancid smell; and belladonna and opium diminish secretion and cause a dryness of the mucous membrane to which bacterial activity may be superadded.

(6) Occupations have also a great deal to answer for as regards foul breath. Milkmen, or those continually working in milk, have a peculiar odour owing to constant contact with the *B. butyricus.* The reason of this is probably the direct transference of the bacillus by the fingers to the nose, with consequent rhinitis. The same theory applies to workers among skins and furs who have a peculiar animal odour. Those who work with phosphorus, lead or brass, have a peculiar metallic odour from their breath, which is associated with rhinitis and "spongy" gums.

(7) Many nervous diseases cause an odour from the breath, such as is found in paralysis and apoplexy. With the foul breath which frequently follows a hemiplegic attack you are doubtless quite familiar. Mental dulness and physical disability prevents proper cleansing of the lips, teeth, and tongue; thus sordes accumulate and fœtor is produced.

Note, therefore, the importance in such cases for regular cleansing by the nurse.

The pathology of foul breath caused by conditions other than organic disease and foreign bodies is somewhat complicated. It can be considered under three heads:—

(1) Imperfect secretion of the glands, both mucous and albuminous. This occurs in atrophic rhinitis, rhinitis and pharyngitis sicca, in glycosuria, and under the influence of drugs such as belladonna, opium, etc.

(2) Deficient leucocytosis and absence of lymphoid elements such as occurs in atrophic rhinitis, a disease characterised by complete disappearance of all the normal lymphoid structures and loss of the phagocytic action of the leucocytes. Under such conditions bacteria grow rapidly, and fœtor results.

(3) Action of bacteria. Some are present in every variety of fœtor. I am indebted to Dr. Wyatt Wingrave, who has exhaustively studied these and other discharges at the Central Throat and Ear Hospital, for information regarding the different micro-organisms which are responsible for fœtor.

The *B. proteus vulgaris* is of frequent occurrence whenever decomposition is taking place, as in caseous rhinitis, lacunar accumulations in the tonsils, pyorrhœa alveolaris, and in all dental troubles, together with ulcerations of the mouth and in chronic suppuration of the ear.

The *S. refringens* (*S. fœtida*), accompanied by fusiform bodies (Vincent's bacilli), are associated with all fœtid accumulations in the throat, nose and ear.

The *B. butyricus* is very common in milk-fed patients and in those engaged in dairy work, also in infants fed from the breast.

The *B. coli communis* and the *B. subtilis* are very rarely absent from oral and pharyngeal infections, while yeasts and torulæ give the peculiar odour to beer drinkers and those subject to glycosuria.

Other fœtor producing organisms are:—

B. fœtidus ozæna.
B. pyocyaneus.
B. lactis erythrogenus.

Since most of these bacilli flourish best without oxygen, it is, therefore, essential to curtail their activity by a free ventilation of the parts. The *B. proteus vulgaris* is a most active cause of fœtor and of ptomaines.

Many of these bacilli are associated with different odours or fœtors. This fact depends to a great extent upon the material or nutrient on which they grow, also upon the conditions of heat, light and air.

Most ulcerated surfaces give rise to fœtor, and it depends on the nature of the bacteria, the scavenging power of the leucocytes, and the implication of bone or cartilage, whether the fœtor is pronounced or not.

Malignant disease may be present in the nose, pharynx, or larynx without much, if any, fœtor, but as soon as ulceration occurs, or the bone or cartilage is attacked, then the fœtor becomes very offensive.

Treatment.—Successful treatment of fœtid breath depends, first, upon a clear recognition of the cause; secondly, on the persistent and thorough employment of the methods adopted; and, thirdly, on the intelligent co-operation of the patient. Remedies to overcome fœtor must not be taken in hand in a half-hearted manner; they must be persevered with most thoroughly, and the patient should be instructed in every detail of the *technique*, whether this includes a douche, spray, or insufflation. A mere temporising by the use of "deodorisers" only results in disappointment, if the *fons et origo mali* remains untouched.

The first aim of the physician is to discover the cause of the trouble, and the second to remove it. It is not my purpose to discuss all the intricate surgical procedures involved in the alleviation and the cure of fœtor, but any sinusal disease *must* be seen to. Any nasal obstruction, whether due to hypertrophy or to new growth, should be removed, so that free drainage and ventilation are established. Any abnormality in deglutition should be corrected. Hasty mastication should be forbidden. When the trouble is of dental origin the aid of the dentist is indispensable, and must not be postponed. Hygienic measures should be enforced before and after each meal; the tooth-brush should be thoroughly employed at least twice a day, but especially after the last meal, in order to remove the accumulations which if left *in situ* naturally tend to ferment during the night. The brush should be used with a vertical rotatory movement to sweep the interstices between the teeth. Lacunar accumulations in the lingual or faucial tonsils should be evacuated, any ulcers should be touched with pure "phenol," and, if extensive keratosis be present, the tonsil should be removed, either *en masse* or by *morcellement.*

Suppurations of the middle ear must be treated by antiseptic drops; rhinoliths, foreign bodies in the nose, pharynx, or larynx must be removed. Causes, whether following the use of drugs, or those which are dependent upon occupations, or upon diet, must be attended to, and constitutional and gastro-intestinal diseases must be thoroughly treated.

The chief aim in overcoming foul breath is to treat and remove the immediate cause, which, we have seen, is usually bacterial in origin, whether primary or secondary. With the object of clearing away fœtid accumulations in the nose and naso-pharynx, "solvent" douches must be employed. It is useless merely to employ antiseptics which do not possess the power of dissolving mucin, albumin, and the constituents of crusts. The best ordinary solvent is sodium sulphate (1 per cent. solution), or sodium biborate or carbonate (in 0.5 per cent. solution). The nose should be thoroughly douched with this until the breath-way is free from crusts and caseous matter. Antiseptics can be employed afterwards direct to the membrane by means of sprays. In mild cases, when the fœtor is not severe, and when the mucous membrane is still sensitive, the olfactory function not being destroyed, an atomiser of liquid paraffin containing menthol, oil of cinnamon, or eucalyptus, is preferable, but, if the fœtor be very intense, Dobell's alkaline solution of phenol may be sparingly used.

We must next restore a healthy secretion by gentle stimulation. This can be done in mild cases by using a snuff composed of boracic acid with otto of roses, but, when the disease is very atrophic and secretion scanty, 5 per cent. of lysoform should be added as a powerful stimulant and antiseptic. It need scarcely be added that intra-nasal douching should be employed with the greatest care, and not persisted in for too long a period, owing to the danger of infecting the middle ear through the Eustachian tube. Severe cases of atrophic rhinitis are very tolerant of douches, and require such treatment at frequent intervals. Sea water, boiled and decanted, forms an excellent douche, especially when combined with a visit to the sea air. The nasal and pharyngeal mucous membranes, except in cases of atrophic rhinitis, are very sensitive, and will not tolerate antiseptic solutions of anything like the strength and intensity which the mouth does. Densely hard crusts are painlessly removed by inhalation of steam, camphor being added to the hot water as a stimulant. To facilitate oral hygiene, solutions of lysoform (1 per cent.), sanitas, peroxide of hydrogen, etc., are most beneficial; permanganate of zinc (1 in 500), or zinc chloride (½ per cent.), is recommended in cases of "spongy gums."

Lozenges containing formic aldehyde should be used frequently; they are non-poisonous, and act as powerful deodorants and antiseptics.

It is important in many cases of subjective foul breath, such as ozæna, etc., to get your patient's confidence by reducing at least, if not overcoming, the fœtor. With the help of a snuff composed of lysoform, boracic acid, and otto of roses, the unhappy sufferer from ozæna may often be rendered fit for the society of his fellow-men and enjoy life.

The treatment of such conditions as bronchiectasis, pulmonary gangrene, gastro-intestinal and other diseases causing fœtor of the breath, fall under the province of the general physician, and is beyond the scope of this paper.

NEURITIS CONSEQUENT UPON CIRRHOSIS OF THE LIVER.

By MAURICE KLIPPEL, M.D.,

Physician to the Paris Hospitals.

[Specially Reported for this Journal.]

Peripheral neuritis in the course of alcoholic cirrhosis of the liver occurs at two stages: In some instances it supervenes during the development of the cirrhosis, even quite at its apparent onset, while in others it only occurs at the terminal period when cachexia is imminent. The first group of cases are specially interesting on account of the severity of the symptoms.

Neuritis associated with hepatic cirrhosis presents very severe symptoms and well-marked lesions. The victims are usually old-standing alcoholics, or are, at any rate, addicted to the abuse of alcoholic beverages. The toxic agent is the undoubted factor, whatever may have been the particular variety of beverage: wine, spirits, bitters, etc. Even wine and beer, when taken in excessive quantities, may determine the disease. In a case reported by Porot and Froment the patient drank two or three quarts of wine a day, and a patient of ours took about the same. It may be remarked, however, that it is often impossible to determine exactly what share must be credited to the essences (absinthe, vermouth, etc.) that enter into the composition of the beverages.

It follows that the mode of intoxication cannot be subjected to any hard and fast rule, but the soil on which the cirrhosis and the polyneuritis develop possesses special importance. In most instances the patients are young women between thirty and forty years of age, and the question arises whether this fact is due to their being more addicted to drinking liqueurs such as absinthe, mélisse, etc., than mere spirits or wine. This seems hardy probable.

The further question arises whether the frequency of neuritis in young women is to be ascribed to a peculiar vulnerability of the nervous system in the female sex; but here, again, no proof is forthcoming. There is, however, one other factor that prepares the soil in conjunction with alcohol, viz.: pulmonary tuberculosis, although the way in which it acts has not so far been explained.

Alcoholic hepatic cirrhosis is frequent enough, as we all know, yet polyneuritis is much less common, so much so, indeed, that Dr. Guillaumot in a recent thesis was only able to find eighteen cases in medical literature, though, since attention has been called to it such records may be more numerous.

Our first case is that of a woman, æt. 37, who indulged in wine and various other alcoholic drinks, especially rum and bitters. She had in all probability suffered from syphilis, for she had had three miscarriages and had been treated with mercury. For twelve years previously she had been suffering from digestive disturbances, with pain in the right hypochondrium, which had become much more prominent of late. The symptoms of neuritis only made their appearance about a month before her admission to the Tenon Hospital. They consisted in fatigue and increasing weakness of the lower limbs. Her legs gave way under her, and she was unable to stand. The paresis steadily became more marked, she became quite impotent, had to take to her bed, and complained of lightning pains in the limbs. On examination we found that she was quite unable to stand or walk, the legs were limp and could not be raised from the level of the bed. There was some diminution of muscular strength in the upper limbs with slowness of movement. She could not grasp objects. Marked loss of sensation and painful sensations in both lower limbs. No sensorial disturbances. Memory was enfeebled with slight cerebral torpor, but no delirium.

The greatly hypertrophied liver reached down to the umbilicus, it was tender on palpation, which gave rise to a spasmodic cough. The collateral circulation was very marked, but not much ascites or œdema. The spleen was hypertrophied, no jaundice, no loss of colour of the fæces. She passed a quart of urine in the twenty-four hours, of a reddish colour and hæmapheic reaction. Pulse 120, temperature 100° F.

She died three months after from progressive cachexia without any particular change in the symptoms.

Post-mortem, we found ten or twelve pints of ascitic fluid of a lemon-yellow colour, marked hypertrophy of the liver and spleen, and adhesions of the abdominal organs to each other. Under the microscope the liver displayed the usual lesions of hypertrophic cirrhosis, with fatty degeneration. Diffuse sclerosis of the pancreas. The sciatic, median, external saphenous, and anterior tibial nerves were found to exhibit the ordinary lesions of alcoholic neuritis.

The second case was that of a woman, æt.38, who had been especially addicted to wine. In this case the symptoms began with hæmorrhages—hæmoptysis and metrorrhagia associated with digestive disturbances: loss of appetite, frequent vomiting, and slight malleolar œdema.

She was admitted on February 6th, 1906, in the following state:—Slight icteric tint of the skin and mucous membranes, a furred tongue, spongy gums, and marked emaciation. The greatly hypertrophied liver came five fingers' breadth below the false ribs in the nipple line. It was hard to the touch, but not deformed. No hypertrophy of the spleen, nothing in the lungs. Pulse 120, nothing in the heart; urine scanty, highly-coloured, contained much pigment and indican. Fæces somewhat pale. Abolition of tendon reflexes, cutaneous reflexes intact. Marked hyperæsthesia in lower limbs, with hyperæsthesia of the upper limbs and thorax. Great loss of muscular strength in the lower limbs which, when raised, fell flaccid on the bed. Pressure of the muscles caused severe pain. Incontinence of the sphincters. No psychical troubles, though at night there was mild delirium and intense restlessness.

She improved to a slight extent, then the upper limbs became paralysed in their turn, the amyotrophy increased, and she had visual hallucinations during the day. A fortnight before death this woman fell into a semi-comatose state, which persisted till the end. Post-mortem there was pronounced hypertrophy of the liver, which was cirrhotic and was undergoing fatty degeneration. The nerves of the lower limbs displayed the usual lesions of alcoholic neuritis: segmentation of the sheaths, multiplication of the nuclei, with marked sclerosis of the connective tissue.

Neuritis that makes its appearance at the ultimate stage of hepatic affections, especially cirrhosis, is less frequently met with than the preceding. The reason is, doubtless, that the neuritis in question is not well marked and requires to be carefully looked for, indeed, it may be quite latent, its existence only being recognised on microscopical examination.

A woman, æt. 56, much emaciated, no ascites, merely some peri-malleolar œdema, was suffering from generalised amyotrophy, most marked in the lower limbs. Motion was retained, but was imperfect. The reflexes were normal and there were practically no sensory disturbances.

In this case, therefore, the most striking symptom is the muscular atrophy, which is usually limited to the extremities and never attains the severity of the amyotrophy in the cases described above. Moreover, the cases differ also in their pathological anatomy. In these cases the nerve fibres do not show the central disaggregation of the myeline sheaths, but merely a thinning and fragmentation of the myeline; in other words, there is segmentary, but attenuated, degeneration. It sometimes happens that segments of nerves undergo degeneration and completely disappear. The vessels are thickened and are not infrequently the seat of obliterating endoarteritis.

Neuritis of the cachectic period of hepatic cirrhosis differs from the other cases not only in the symtomatology, but also in the lesions, and in all probability it is not due to ethylic intoxication at all, but to the nutritive disturbances associated with the cachexia.

It will be seen that the clinical picture of poly-neuritis associated with cirrhosis of the liver strikingly resembles that of classical alcoholic neuritis, but on scrutinising the cases more closely certain differences will be perceived.

In this form of neuritis we witness rapid extension of the polyneuritic phenomena, which do not remain limited to the lower limbs, but soon attack the upper limbs, causing almost complete functional impotence. Even the cranial nerves may become involved, and in one of their cases Porot and Froment mention an instance of ptosis which appeared to form part of the nervous changes. Disturbances of the pneumogastrics have also been met with as in our second patient. Disturbances of the sphincters, giving rise to incontinence or retention of fæces, are more frequent here than in uncomplicated alcoholic neuritis. It must be admitted that these disturbances have not always the same significance, some being the outcome of psychical changes associated with the polyneuritis, while others are due to lesions of sympathetic nerves or of nerve filaments innervating the striated sphincter of the urethra. This distinction is necessary because vesical incontinence is not, in most instances, due to mental disorder, whence it follows that sphincter troubles are fairly peculiar to associated neuritis. We must also insist on the distressing nature of the polyneuritic pains in question. The pain may be spontaneous or provoked, and is practically never wanting in cases of cirrhosis associated with polyneuritis. With regard to the psychical troubles, all authors are agreed in considering them of frequent occurrence. When characterised by delirium they are particularly grave, and are sometimes accompanied by convulsions that culminate in the terminal coma.

The liver symptoms are classical—increase in size of the organ, the lower border whereof may reach down to the anterior superior iliac spine, and usually comes at least five fingers' breadth from the edge of the false ribs, but is not deformed. Marked jaundice is exceptional, but there is often a yellowish tinge. The urine is rather scanty, and is sometimes albuminous, is laden with modified bile pigments, and contains urobilin and indican. Paleness of the face is tolerably frequent. The digestive disturbances are not peculiar, but mention must be made of hæmorrhage, early in point of date and grave in point of amount. The blood may come from the gums, œsophagus, or even the uterus, or we may have purpura or profuse epistaxis.

Hepatic inadequacy is manifested by a certain number of symptoms; there is almost always urobilinuria and indicanuria, but alimentary glycosuria, on the other hand, is rare.

As a rule, polyneuritis associated with cirrhosis occurs in connection with the hypertrophic form of the liver affection, but it may also be met with in the atrophic form, as in the case of an old man who presented atrophic paralysis of the lower limb muscles, in whom, in addition to the neuritis, the liver was diminished in size, and displayed microscopical lesions like those of Laennec's atrophic cirrhosis. It may also be mentioned that ordinary alcoholic polyneuritis is accompanied by a slight increase in the size of the liver, due, not to cirrhosis, but to fatty degeneration of that organ—a fact which had escaped observation until the polyneuritic pain led to the patient being closely examined.

Our observations lead us to believe that the liver lesions and the neuritis do not progress hand in hand. While in some instances the phenomena of neuritis set in first, the cirrhosis only becoming appreciable later on, in others it is the symptoms of hypertrophic cirrhosis, especially hæmorrhages, that attract attention. But the commonest signs, after all, are disturbances of liver function, more or less discrete, more or less ill-defined, that usher in the pathological state.

Polyneuritis associated with hepatic cirrhosis runs a definite course. In contrast with that of simple polyneuritis, it looks grave from the onset. The trophic disturbances and the symptoms of paralysis steadily progress, and death usually supervenes in a few months from hepatic inadequacy or extension of the neuritis. Acute tuberculosis may precipitate the fatal issue. Less frequently, after an acute period of variable duration, we get progressive improvement, which may go on to complete recovery. Unquestionably, the generalised neuritis of cirrhotic subjects presents certain peculiarities (rapidity of the paralytic phenomena and amyotrophia, sphincter troubles, delirium, etc.), but these peculiarities do not suffice to distinguish it from the polyneuritis of non-cirrhotic subjects. As a matter of fact, these symptoms may be met with in the course of ordinary polyneuritis, and even the evolution of this neuritis is not pathognomonic; in short, the gravity of the condition is due to the changes in the liver, and not to the polyneuritis.

Similarly, this cirrhotic polyneuritis cannot be differentiated from simple alcoholic neuritis by the anatomical lesions. In almost all cases the liver lesions are those of hypertrophic cirrhosis with fatty degeneration, and the constancy of the lesion in question is confirmed by all writers on the subject. In Hudelo and Ribierre's case, which appeared to be an exception to this rule, the polyneuritis did not take place in a cirrhotic subject, but in a patient suffering from intense jaundice, and the liver presented fatty degeneration similar to that met with in hypertrophic cirrhosis. In these patients both lobes of the liver are uniformly enlarged; its weight varies from 4½ to 7 lbs.; it is usually hard, and on section its parenchyma shows yellowish nodules closely packed in a much thickened fibrous stroma. Perihepatitis is also frequently met with in this association.

The microscope shows diffuse lesions involving the constituent elements of the liver; the connective tissue forms big fibrous bands separating the islands of fragmented parenchyme, in the middle of which are the sub-hepatic veins and the porto-biliary spaces. In our own cases we found changes in the biliary canals, the portal veins, and even in the branches of the hepatic artery. There were, in addition, newly-formed biliary canals and numerous embryonic cells, many of which were undergoing fatty degeneration, with some that contained an excess of bile pigment.

In cases where it was possible to examine the nerves microscopically, we found the same changes in the myeline sheaths and axis cylinders as in cases of alcoholic neuritis. These lesions had indirectly set up changes in the anterior root cells of the cord, which displayed chromatolysis, either central or diffuse. Lastly, the muscle fibres of the atrophied muscles were diminished, and the connective tissue cells increased in size and number. In subjects who had presented cerebral disturbances, we found toxic neuro-cerebritis, but the vessels and meninges were intact. It will be seen that the neuritic lesions in question are in every respect identical with those of purely alcoholic polyneuritis.

We now come to the pathogenesis of polyneuritis accompanying hepatic cirrhosis. The neuritis has been attributed to auto-intoxication produced by inadequacy of the hepatic functions. But is this really the case? Dr. Hayem records the case of a patient, æt. 48, who presented symptoms of neuritis characterised by pain in the upper limbs and paresis of the hands, soon followed by similar symptoms in the lower limbs. Simultaneously he noted abolition of the reflexes, with disturbances of the sphincters and subdelirium. These clinical features, as well as the course of the disease, prove that it was really a case of neuritis complicating cancer. On the other hand, Dr. Gouget's observation also fails to show the dependency of the neuritic lesions on auto-intoxication of hepatic origin. The case was that of a woman, æt. 23, suffering from paresis of the extensor muscles of the hands and feet, who had reached an advanced stage of cachexia. The liver and spleen were both hypertrophied, but there was little ascites. The neuritic manifestations followed the liver disease, for they did not make their appearance until two months after her admission to hospital, so that they could not be put down to alcoholic intoxication, especially as the woman had given up drinking some time before. Dr. Gouget therefore thinks that, although alcohol may have prepared the soil in this instance, the neuritis ought rightly to be ascribed to organic poisons. It must, however, be borne in mind that in this case the nerves did not present the lesions of true neuritis, but only degenerative changes. This case must therefore be classed among the cachectic neuritis, and not with those obviously associated with hepatic cirrhosis.

Confronted by these divergencies, Drs. Castaigne and Sainton decline to regard the cirrhosis as the principal factor in the production of the neuritis, although they conceded that it may exert an indirect influence in that direction. They hold that the cirrhosis hampers more or less the antitoxic functions of the liver, and thus facilitates the action of alcohol on the peripheral nerves, whence the neuritic manifestations. This enables us to explain the infrequency of neuritis in the course of hepatic cirrhosis, the patients suffering therefrom becoming aware of the gravity of their plight, or, following their doctors' advice, often desisting from further alcoholic indulgence.

To sum up, generalised polyneuritis supervening in association with cirrhosis of the liver does not differ in any way from non-complicated alcoholic neuritis. The liver affection, by hampering the antitoxic function of this organ, renders the peripheral nerves more vulnerable, and allows the neuritic changes to progress with a rapidity proportional to the gravity of the hepatic lesion.

RECENT ADVANCES IN
THE SURGICAL KNOWLEDGE AND TREATMENT OF SYPHILIS. (a)

By D'ARCY POWER, F.R.C.S.Eng.

There is an obvious advantage in reviewing the knowledge of every scientific subject from time to time, inasmuch as advances in one branch often lead to progress in others which appear at first sight to be remote.

In the case of syphilis, the diagnosis and treatment of diseases of the bones and joints have been greatly helped by progress in optics leading to the production of better microscopes; by advances in physics resulting in the discovery of Röntgen rays; and by the rapid progress of pathology, which is itself based on physics, chemistry and biology.

Histology has enabled cases of tumor albus or white swelling of joints to be classified as tuberculous and gummatous. The distinction between these two forms was thought at first to be absolute. Modern views tend to show that, in some cases at least, a gummatous synovitis is really a tuberculous inflammation infecting the joints of those who inherited syphilis. Instances are given, and the conclusion is reached that, whereas, a few years ago a chronic arthritis presenting the characters of a white swelling could be spoken of dogmatically as tuberculous or gummatous, it is now necessary to form intermediate groups due to the microbic infection of tissues modified by the action of the spirochæte pallida whether this organism has been acquired or inherited. Tubercle and syphilis form the most frequent combination, but some varieties of pneumococcus and staphylococcus show a special liability to invade syphilitic tissues, whilst an attack of influenza may prove to be the starting point of a gummatous arthritis in syphilitic patients.

The Röntgen rays have enabled important advances to be made in the knowledge of syphilitic inflammations of bones and joints. The skiagraphic appearances in syphilitic osteitis and arthritis differ from those seen in analogous inflammations produced by tubercle and rheumatism. Radiographs, too, show that syphilitic inflammation of the bones may begin at a much later period than has hitherto been thought possible, and in persons who might reasonably have supposed themselves free from any taint of inherited syphilis.

Attention is further drawn to the interaction of tubercle and syphilis by the narration of a series of cases in which young persons have presented the appearances characteristic of a leukoplakic tongue and have died afterwards of tuberculosis. The peculiar characters of a leukoplakic inflammation, it is contended, would not have been impressed upon the tongue in these cases if the patients had not inherited syphilis; indeed, in the absence of any syphilitic taint the tongue might entirely have escaped inflammation, for primary tuberculosis of the tongue is not of common occurrence. It would be extremely interesting to ascertain whether these children were the "healthy" offspring of parents who had been "cured" of syphilis before marriage, whether they were born after a series of miscarriages due to syphilis, or whether they had suffered in their youth from other signs of inherited syphilis.

The advances in the surgical treatment of syphilis have proceeded along two main lines. First, a thorough belief in the curative value of mercury when properly administered, the object of treatment being to cure the disease and not merely the symptoms complained of by the patient; secondly, a clear comprehension of the limitations of treatment by iodides. It is impossible for the tissues to rid themselves of large masses of inflammatory syphilitic products even with the help of iodides. It is better therefore to remove gummata, mucous patches, condylomata and similar masses by ordinary surgical means rather than trust to their absorption by Nature. Iodides may then be given with very satisfactory results, but they should always be followed by a mercurial course.

CLINICAL RECORDS.

CASE OF ERB'S PARALYSIS FROM TRAUMATISM. (a)

By G. HAMILTON, F.R.C.S.,

Surgeon, Liverpool Royal Infirmary.

Four months ago, J. M'C., æt. 38, fell down five steps on to the tip of his shoulder, violently stretching the whole of the structures between the neck and shoulder. His doctor states that there were bruises about the shoulder, but no fracture or dislocation. He was X-rayed when he came under my care four weeks ago, and no evidence of injury to the shoulder-joint or clavicle was found. There is marked wasting of the following muscles—deltoid, infraspinatus, supraspinatus, biceps (coraco brachialis?), brachialis anticus, supinator longus. The pectorals, trapezius, latissimus dorsi, flexors and extensors of wrist-joint are unaffected.

His symptoms came on immediately after the accident, when he found that his right arm hung helplessly by his side. There is inability to raise the shoulder, paralysis of the external rotators of the shoulder, inability to flex the elbow or to supinate.

Although carefully tested in the manner advocated by Head and Sherren, no loss of sensation has been found except in an area about the size of a five-shilling piece to the outer side and a little above the insertion of the deltoid. Here the patient had some difficulty in distinguishing the head from the point of a pin, and when gently brushed with cotton-wool he feels everywhere except over this area, so that it is a change in, rather than a total absence of, sensibility. The impaired area for distinguishing heat and cold is just a little larger than that of touch. Another interesting feature is, that the supra- and infraspinatus, detoid, clavicular portion of pectoralis major and biceps act to a mechanical stimulus. The triceps jerk is present.

(a) Abstract of a paper read at a meeting of the Medical Society of London, May 11th, 1908.

(a) Paper read before the Liverpool Medico-Chirurgical Society.

Dr. Bradshaw kindly undertook the electrical changes, and reports absence to Faradic current in all the paralysed muscles and reaction of degeneration in several, notably the deltoid. The "upper arm type," or Erb's paralysis from traumatism was described by him, mostly in connection with obstetrical palsies. In the case under discussion we are forced to the conclusion that the motor fibres of part of the fourth and those of the whole of the fifth and sixth cervical nerves have been torn. If we admit this, it is most difficult to explain the almost total absence of afferent nervous phenomena. It is unlikely that motor fibres *alone* have been torn.

In a somewhat similar case to this, reported in "Brain" by Warren, the fifth and part of the sixth nerve was found at an operation to have been torn, and absence of contraction of the paralysed muscles was proved by stimulating the lower end of the torn nerve.

As Head and Sherren have pointed out, when the median nerve is divided, sensation is lost over a considerable part of both the index and middle fingers, but over the palm, the area said by anatomists to be supplied by this nerve, sensation is usually *diminished* and not completely abolished. Similarly, division of the ulnar nerve produces complete insensibility of the little finger and of a variable portion of the ulnar aspect of the palm, but *partial* loss is found over a larger area of the palm; the explanation generally given being that there the nerves overlap.

The overlapping theory has not, however, been found to explain the unequal sensory phenomena in the case of the ulnar and median nerve, when divided separately. In our case the man could not appreciate cotton-wool gently rubbed over the small area above described, or heat and cold, or two points of a pair of compasses, and yet he could feel some pain. By the overlapping theory, he ought to be able to appreciate these higher forms of stimulation as well as pain.

Operation (five months after accident).—A curved incision about six inches long was made following the posterior border of the sterno-mastoid and upper border of clavicle, and a flap was thrown backwards. It was soon found that the upper cords of the brachial plexus had been dragged through the fibres of the scalenus anticus, and that the chief injury was to the cord formed by the fifth and sixth nerves. This cord appeared to be much larger and thicker, and part of it was replaced by fibrous tissue. Unipolar excitation with the Faradic current gave a response only in the lower half. The strength of the current was deemed efficient since stimulation of the also exposed fourth nerve produced unmistakable movement. Accordingly, about an inch and a quarter of this fibrous material was removed and its place taken by a graft from a fox terrier's sciatic. The graft was fixed in position by two fine silk sutures at each end. The wound was closed without drainage, and healed by first intention.

On examination the morning after the operation the cotton-wool test seemed to be better marked over the small insensitive area above mentioned, but this area soon became as before the operation. The patient was carefully examined four and a half months after operation, and distinct improvement in his biceps flexion was found; otherwise he remained as before. The graft had given him no trouble.

OUT-PATIENT'S ROOM.

METROPOLITAN HOSPITAL.

Cases of Retroflexion.

By EARDLEY HOLLAND, M.D., M.R.C.P., F.R.C.S.

Amongst the out-patients were two cases of retroflexion which presented special features. The first was a woman, æt. 25, who had had one child two years ago. Since then she had had five miscarriages, all about the second month. She also complained of minor symptoms, such as profuse menstruation and backache. On examination a fixed and somewhat tender retroflexion was discovered. The appendages were free from disease. Dr. Holland said that the retroflexion in this case undoubtedly arose during the puerperium two years ago. On more careful inquiry into the history of this puerperium, the patient said she got up on the tenth day, but had to return to bed almost immediately for two or three days because of slight bleeding, which her doctor treated with hot douches. Dr. Holland thought this a most important case. The majority of retroflexions arise in the puerperium. The time of their appearance is most constant about the tenth day, when the uterus has again entered the pelvis. The only symptom caused is bleeding; this is never profuse, and is usually quite transient, resembling the early lochia; it is very different from the sudden hæmorrhage which may also arise about this time from a retained piece of placenta. The patients are usually primiparæ. He pointed out that these cases usually escape recognition, which is most unfortunate, because a fixed retroflexion, as in the case under consideration, may be one of the most troublesome affections from which a woman may suffer, and which, when it has been allowed to become established, is difficult and wearisome to treat. If a woman in the puerperium, therefore, has a slight hæmorrhage, she should be examined at once for retroflexion, and since in many of the cases this one symptom —bleeding —may even be absent, he considers it advisable to examine all puerperal patients as a routine on the fourteenth day. If then such a retroflexion be discovered, its treatment is simple and effectual. All that is necessary is to replace the uterus with the fingers and to make the patient lie in the semi-prone position for the next few days instead of on her back. At the same time ergot and hot vaginal douches should be given to ensure efficient contraction of the uterus. It is most inadvisable to use a pessary in the early days of the puerperium, as this stretches the vagina and permanently interferes with its proper involution. If these points were sufficiently known and carried into practice, he considered that, on the theory that prevention was better than cure, very many fewer cases of retroflexion would be met with in practice. With regard to the treatment of this case at the present time, the first indication was to overcome the fixation and render the uterus mobile, and the second to replace it in its proper position and maintain it there. For the former, tampons soaked in a 10 per cent. solution of ichthyol and glycerine must be inserted high up in the posterior vaginal fornix every night before the patient goes to bed, and taken out again in the morning. Before inserting each tampon, and after removing it, a hot vaginal douche of lysol, ½ drm. to the pint, at a temperature as hot as can be borne, should be given. At the same time the bowels should be regulated by a saline purgative every morning. By these means adhesions, if not too extensive, will be absorbed, and in two or three weeks the uterus will probably be found mobile. Of course, in cases of retroflexion due to pelvic inflammatory disease, accompanied by disease of the tubes, and bound down by dense adhesions, these measures will have no effect in rendering the uterus movable again. It is only in such cases as the present, where adhesions are slight, as is usually the case in uncomplicated puerperal retroflexions, that these methods will be efficacious. When the uterus is again quite movable, it should be replaced bimanually, and kept in position by a well-fitting Hodge's pessary.

The second had been a similar case which had presented precisely the same history, and had been treated on the lines just laid down. She was first seen six months ago, and was now four and a-half months pregnant. At the time of the second and third expected menstrual periods during her present pregnancy, she had suffered from slight hæmorrhage, and had been instructed to remain in bed for three or four days at the time she expected her periods. There is no doubt that, especially in women who have had repeated abortions, the uterus is in a very irritable condition at the time of the menstrual epoch, and abortion is then apt to occur. Dr. Holland removed the pessary, as the uterus had now risen up out of the pelvis, and displacement, therefore, could not occur.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

OPERATION FOR ANKYLOSIS OF ELBOW.—MR. EDRED CORNER operated on a young man, æt. 17, who had been admitted for the relief of the condition of ankylosis of the elbow. The history was: Eight years previously he had fallen on his elbow, and though it was not much injured at the time, the joint became swollen some time afterwards. The arm never gave him sufficient pain to make him consult a medical man. The swelling gradually subsided, and the joint became stiff. Unfortunately for him, the ankylosis took place with the arm nearly in the fully-extended position. When the patient began to do some work, he found that it was impossible for him to do much with the arm fixed in this position. He therefore came to the hospital with a view to obtaining some relief. To obtain a good movable elbow, Mr. Corner said, is naturally the result which a surgeon would like to secure. This might be done in two ways—by means of an arthrotomy dividing the ankylosis, and following up the operation with active, passive movements and massage, or the elbow might be excised. The results which are seen from excision of the elbow are not such as should encourage surgeons to perform that operation more than is absolutely necessary; at best the arm is weak, and of little value. To meet this disadvantage, he had made it a rule to retain the olecranon where possible in all cases. By this means he had found that it was possible to eradicate all the disease, and to restore to the patient a strong, useful and serviceable limb. In one case even a skilled radiographer examined the joint and took a radiograph two years after the operation, and reported that there was nothing abnormal in the lower end of the humerus and the upper end of the radius, whilst, as a matter of fact, these had been removed in greater part at the operation. This, he thought, was the best testimonial which he has met with regard to Nature's restoration of the bony parts after operation. With regard to the present case, the elbow has been ankylosed for upwards of eight years, during which period the muscles of the upper arm have atrophied to such an extent that, even if he succeeded in obtaining a movable joint, there would not be sufficient muscular power to prevent the limb from becoming flail. Under these circumstances, it was undesirable that an attempt should be made to give the patient a movable joint, and he must merely content himself with freeing the joint sufficiently to allow ankylosis to take place again with the arm in such a position as to enable the patient to do some work. An incision was made in a longitudinal direction over the back of the arm on the outer side of the olecranon. The outer part of the tendon of the triceps was split, and the elbow-joint opened. It was then seen that the muscle remained as a yellowish-brown, soft mass. The ankylosis was found to be due to the adhesion of the under-surface of the tendon of the triceps to the lower part of the back of the humerus. When this had been freed with a knife and an elevator, it was possible, by stretching the triceps, to flex the elbow to an angle of about 30 degrees. The tendon of the triceps was then sutured with interrupted stitches of fine silk, and the skin wound closed with interrupted salmon gut. The arm was dressed with gauze, and maintained in the flexed position by a bandage arranged in a figure-of-eight round the fore and upper arms. The arm was tethered to the side by means of a bandage passed round the waist, enclosing it with two half-hitches. Mr. Corner said a splint was not used because it was desired that the arm should be maintained at less than a right angle, for which position there was no available splint, and the arm is much more comfortable when merely bandaged up.

The dressing will be taken down in two days' time to allow of a further examination of the power remaining in the muscles. If there should be any promise of its return, massage, movement, and electrical stimulation will be begun. If, on the other hand, it is decided that muscular power cannot be restored, then the elbow will be allowed to ankylose in a good position.

TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, MAY 8TH, 1908.

The President, Sir THOMAS BARLOW, Bart., in the Chair.

DR. STILL showed a girl, æt. 7, from whose stomach a mass of hair, welded together to form a complete cast of the organ, had been removed. She had been admitted to King's College Hospital for vomiting and an abdominal tumour, stretching from the left hypochondrium to the midline. An exploratory operation had revealed the nature of the tumour, and the removal of the hair had led to a successful issue. The hair had come from the patient's own head, by whom it had been pulled out and swallowed. Dr. Still referred to 14 similar cases on record, 13 of whom were girls.

Mr. C. A. BALLANCE stated that he had successfully treated a similar condition in a woman in whom the hair had traversed as far as the jejunum.

Mr. WATSON CHEYNE showed a patient illustrating spontaneous disappearance of recurrent carcinoma of the breast. The patient was a woman, æt. 51, whose breast had been amputated for scirrhus carcinoma on October 2nd, 1901. The nature of the growth had been proved microscopically. Early in 1903 several small subcutaneous nodules had developed over the chest and upper part of the abdomen, which were thought to be certainly cancerous. On October 1st, 1907, she wrote to say that three years before the lumps had disappeared concurrently with the menses, and in the absence of any medical treatment. This was found to be correct, and now there were no nodules or other evidence of recurrence.

The PRESIDENT and Mr. C. A. BALLANCE showed a boy, æt. 5, in whom a rupture of the upper cord of the brachial plexus had occurred during childbirth, and who had been treated by operation 10 months afterwards. Before the operation the muscular reactions, when examined under chloroform, showed that the deltoid, biceps, brachialis anticus, coraco-brachialis, and supinator longus were totally paralysed. It was found that the fifth cervical nerve was ruptured just where it joins the sixth, and reunion was effected by silk suture. After four years' absence the child returned to England, and it was found that the paralysed muscles had completely recovered. Complete supination, however, could not be effected, and shortening of the pectoralis major limited the movements of the arm.

Dr. POYNTON said that it was difficult to know when to operate in such cases, since in some many cords were partly affected, and many cases recovered very well without operation.

Dr. PURVES STEWART showed a man, æt. 50, who had been the subject of a gross lesion of the post-central gyrus associated with astereognosis. Symptoms referable to a lesion in the left cortex had started in 1894 or 1895, and had gradually increased until September, 1907, when there were weakness of the right lower face and clumsiness of the right arm, with tingling in the right index and middle fingers. Some aphasia was also present, and later astereognosis of the right upper limb. The right leg became affected, and the steadily progressive right hemiplegia, and intense headache, with the astereognosis of the right hand suggested a gross intracranial lesion in the region of the left post-central gyrus. Mr. Ballance operated on October 28th, 1907, and found a patch of thickened yellow pia-arachnoid occupying the middle third and adjacent part of the lower third of the post-central gyrus. The diseased area was removed. At the time of exhibition the aphasia had largely cleared up, but there still remained weakness of the right lower face and right arm, and astereognosis, as before. The reflexes in the right upper limb were increased.

Dr. J. BARNES BURT showed three cases of patients with gout showing destructive changes in bone. Case I.—A man, æt. 67, had suffered from gout for 25 years, and had not been able to walk for 11. A skiagram showed central necrosis of bone at the proximal end of the first phalanx of the index finger, and in the corresponding phalanx of the next finger, and also several punched out areas of necrosis in the distal end of the second phalanx of the index finger.

Case II.—A woman, æt. 36, who had suffered from gout for 5 years. The skiagram of the left hand showed a necrotic area, about the size of a pea, in the distal end of the second phalanx of the middle finger.

Case III.—A man, æt. 55, who had suffered from gout for 5 years. A skiagram showed a right area in the distal end of the first phalanx of the index finger. He pointed out that the areas of necrosis were not apposing tophi, and could not be produced by pressure from tophi, as is usually supposed.

Dr. POYNTON said that he thought Ebstein's view of the pathology of uratic deposit would prove to be correct, that there was a primary necrosis, and that by altered chemical reaction biurate of soda was produced locally.

Mr. C. H. FAGGE showed a woman, æt. 50, in whom parts of the femoral artery and vein were excised for recurrent sarcoma. A growth had been removed from the inner side of the right thigh in September, 1906, and proved to be a spindle-celled sarcoma, with many myeloid cells. A recurrent growth was removed in July, 1907, and a second in December, 1907. At this operation it was found necessary to ligature the femoral artery and vein above and below, and to remove them with the long saphena nerve. The circulation of the leg was quite restored on her discharge 18 days later.

Mr. C. H. FAGGE also showed a man, æt. 26, who had suffered from an aneurysm of the common femoral artery. The aneurysm and common femoral vein had been excised. The tumour had been noticed for eight months. At the operation the right external iliac artery was exposed and ligatured, and afterwards the deep epigastric and superficial femoral arteries. The aneurysm was then dissected out, and during its removal it was found necessary to remove the common femoral vein also. Sensation and power returned in the leg and foot after 48 hours, but the pulse in the tibial vessels could not be felt a month after the operation.

Dr. G. A. SUTHERLAND showed a case of "Scleroderma" in a boy, æt. 5½. For three weeks the skin of the face had been noticed to be tense and hard. The induration also affected the eyelids, scalp, neck and extremities, and to a less extent the trunk. The tongue was distinctly hard. The boy's general condition and development were good.

Mr. ALBERT CARLESS showed a man, æt. 37, with multiple symmetrical lipomata. The condition began as a small lump on the face in 1905. Subsequently many large fatty tumours, showing striking symmetry, had developed. Some had been removed by operation, which had shown that the growths were limited and localised, and that they tended to burrow and become adherent to surrounding parts.

Mr. P. MAYNARD HEATH showed a girl, æt. 6½, who suffered from caries of the spine associated with clubbing of the fingers and toes. The disease was of four years' duration, and associated with great thoracic deformity. There was no evidence of lung disease. Occasional attacks of cyanosis occurred.

Dr. F. PARKES WEBER showed a case of multiple idiopathic hæmorrhagic sarcoma of the skin in a man, æt. 52. The disease had started as a pedunculated growth from a wound in the sole of the right foot six years before, which was removed by a medical man. Afterwards small, hard, bluish or purple spots appeared, chiefly in the lower extremities, and from time to time sessile or pedunculated little tumours, which tended to ulcerate and drop off. It was a typical case of the condition described by Kaposi.

Mr. CHARLES A. BALLANCE read the notes of a case of "Arterio-Venous Anastomosis for Senile Gangrene." It was that of a woman, æt. 75, who was admitted to St. Thomas's Hospital, September 20th, 1907, with arterial gangrene of the first, second, and third toes of the right foot. The condition remained stationary for three weeks, but she suffered so much pain that sedatives were required. At the end of three weeks the gangrene began to extend, all the toes became affected, and the discolouration of the skin extended over the dorsum of the foot. On October 17th, 1907, an arterio-venous anastomosis was made in the upper half of Hunter's canal. The same evening an arterial pulse could be felt in the internal saphena vein, and in the veins on the dorsum of the foot. The foot became warm, and the pain was relieved. The discolouration of the skin of the fourth and fifth toes, and of the dorsum of the foot, disappeared. During the next few months the superficial gangrenous patches on the first, second and third toes began to separate. The patient died from gangrene of the large intestine on February 15th, 1908. In the paper comment was made on the case, and on clinical and experimental observations bearing on the subject.

Mr. FORBES ROSS suggested that more surgical use might be made of the fact that ligature of an artery is followed by vasomotor dilatation in the part supplied.

Dr. NORMAN DALTON read the notes of a case of "Leucoderma," the patient having died with symptoms of Addison's disease and cirrhosis of the suprarenals. The patient was an unmarried woman, æt. 35 at the time of death. She had had typical and widely distributed leucoderma (as shown by the photographs produced) for ten years, and her health had been quite good all this time. The only noteworthy point about the skin affection was that the white patches had the faintest shade of pink in them, so that she was brown and pale pink, rather than brown and white. After death, however, the patches were quite white. In July, 1907, epigastric pain and vomiting set in. She became very weak, and was admitted into King's College Hospital on October 4th, 1907. No indications of structural disease in any organ could be discovered. The vomiting continued, and she became weaker. On October 15 she became faint, and died in a few hours from cardiac failure. This final syncope, in conjunction with the vomiting, suggested that Addison's disease was present, although the skin was typically leucodermic, and at the post-mortem the suprarenals appeared to be simply atrophied. On microscopical examination, however, they proved to be cirrhotic. Dr. Dalton did not think that the association of the symptoms of Addison's disease with leucoderma was a mere coincidence, though he could offer no explanation as to why the innocent pigmentary changes, which are so unlike those of Addison's disease, should in any way be connected with the changes in the suprarenals and the gastric and cardiac symptom. He thought it important, however, to recognise that, if these symptoms supervene in a case of leucoderma, some lesion of the suprarenal is probably present, and that the prognosis is correspondingly grave. This case, though rare, is not unique, for McCall Anderson has recorded one of the same kind. Dr. Dalton did not discuss the pathology of leucoderma, but stated that this case might be heard of at a future time in that connection, for Mr. Lenthal Cheatle had found pathological changes in the Gasserian ganglion, corresponding to the white patches on the face.

Dr. **Parkes Weber** asked if there was any evidence, microscopical or otherwise, that the case was not one of pigmentation of the skin originally, with the retention of untouched normal areas, and not true leucoderma.

Dr. **Dalton**, in reply, said that he did not know about the condition at its onset, as he had only seen the patient a short time before death.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, May 1st, 1908.

The President, Mr. **Richard Lake**, F.R.C.S., in the Chair.

Dr. Herbert Spencer gave a short address on the examination of the

PELVIS AND ABDOMEN DURING PREGNANCY,

its advantages and, indeed, its necessity, if women were to have the full benefit of obstetric science at the time of labour. It was a practice he had personally adopted during the last 20 years. Lantern slides were exhibited illustrating the advantages of the examination and the dangers and fatalities resulting from its omission. He advocated external and internal examination at the end of the third month and external examination at the end of the seventh month. Vaginal examination should be gentle: he warned especially against forcible bimanual examination and the eliciting of Hegar's sign as liable to produce abortion. Attention was called to the value of abdominal *ballottement*, and methods of obtaining it were demonstrated on the screen. He stated that the height of the top of the pregnant uterus above the pubes was erroneously stated in English text-books. At the end of the third calendar month it was as high as the promontory (3¾ inches above the symphysis); at the end of the fifth calendar month it was on a level with the umbilicus. The height above the symphysis during the first six calendar months was obtained approximately, by adding half an inch to the number of the month. It could be felt at 2½ inches above the symphysis in all ordinary cases at the end of the second month.

The advantages to be derived from examination during pregnancy were that the fact and the period of gestation, the position of the uterus and the presentation and position of the child were ascertained, and treatment could be applied during the pregnancy. Presentation of the breech and shoulder would thus in many cases be prevented. Contraction of the pelvis could thus be discovered in time to decide on induction of labour or on Cæsarean section, which in such cases should always be successful at the present day. Fibro-myoma was a not uncommon complication of pregnancy, especially in elderly primiparæ, not often requiring interference, but sometimes needing Cæsarean section, as in three of his cases. He had operated on between thirty and forty ovarian tumours which had complicated pregnancy. Two required operation during labour when they were first discovered. The greater number of the cases were not examined during the pregnancy and many complications ensued. Those found and removed during pregnancy made simple recoveries. Even cancer complicating pregnancy was not hopeless: three of his cases with advanced pregnancy remained well after 11 years.

Dr. Seymour Taylor read a paper on

SOME NEGLECTED REMEDIES.

He deprecated the modern tendency to run after new drugs and remedies, and to discard the old methods. Fashion had much to do with modern prescribing, but it was not necessary that the profession should be told, and even mildly coerced, by interested drug vendors, to sell their special form of new remedy. Such an attitude presupposes that pharmacy is not nowadays taught in our medical schools. But, commencing with external applications, Dr. Taylor advocated the use of the seton in some forms of congestive headache, and even in epilepsy. He was convinced that in the latter disorder a judiciously applied seton deferred epileptic attacks, and even rendered them less severe. Venesection, again, is valuable treatment in those diseases where the circulation through the right heart is embarrassed. He quoted three cases, one of chronic bronchitis and marked cyanosis, one of acute œdema of the lung subsequent on mitral obstruction, who were fully bled and both of whom recovered when on the verge of death. The third case was one of suicidal hanging. In this instance the external jugular vein was opened, and life prolonged to the third day. Probably had this treatment been adopted earlier than it was the patient's life would have been spared. But bleeding should never be regarded as a routine practice, as it was formerly. Bleeding was useful in many cases of pneumonia, for example, but chiefly when cyanosis was a marked symptom. The indications for bleeding were afforded by the heart rather than the lung. The blister was also a somewhat neglected remedy, yet it afforded great relief to the acutely inflamed rheumatic joint, and the smart of a blister was more tolerable than the dull throbbing of a swollen joint. Blistering in pericarditis has been revived, and with advantage. Consistency also demands that if we blister a rheumatic knee we should also blister a rheumatic heart, and we do so in many instances with the utmost benefit.

Dr. Seymour Taylor then spoke of the use of many drugs. In the treatment of chlorosis, arsenic, if persevered with, was in numerous instances as efficacious as iron. It must be continued for a lengthened period, and if it acted as a slight aperient so much the better. Sarsaparilla, an old-fashioned remedy, but still retaining the confidence of the laity, as we see it dispensed by itinerant vendors in our country fairs and market places. It is undoubtedly a corrective remedy in some skin affections which are not syphilitic. But its chief efficacy lies as an adjunct to iodide of potassium in the treatment of cutaneous syphilides and of nodes. It should be prescribed in large doses. Other neglected remedies which were referred to were Plummer's pill, in primary syphilis. This remedy should be freshly made. Pulvis basilicus or royal powder, as a febrifuge in children suffering from fever due to gastrointestinal irritation; guaiacum, gum ammoniacum, and copaiba in chronic bronchitis with profuse or fœtid expectoration; galbanum and assafœtida for the relief of intestinal distension, so often a distressing symptom in failing heart; antimony in acute affections of the respiratory membranes; and lastly, musk, which, although a disgusting remedy, had apparently, in two instances, saved lives which, in typhoid fever, appeared to be on the brink of the grave. It was not contended that all, or any, of these remedies were entirely discarded; but it was contended that they might all be more frequently used with advantage, especially in carefully selected cases.

HARVEIAN SOCIETY OF LONDON.

Meeting held May 7th, 1908.

The President, Mr. **D'Arcy Power**, in the Chair.

The following clinical cases and specimens were shown and discussed:—

Dr. Leonard Guthrie showed:—(1) A case of cerebral diplegia in a child, æt. 4, the onset of which was after an attack of measles at 2.

(2) A case of cirrhosis of the liver in a child, æt. 10, with marked ascites There was no evidence of congenital syphilis.

(3) A case of obliterating endarteritis in a woman, æt. 42. The arteries of the right upper extremity were affected and no pulse could be felt. Pain and coldness of the affected limb were present, and there had been troublesome whitlows. There was symmetrical malformation of the clavicles.

Dr. Sutherland showed a case of scleroderma, which had followed a recent attack of measles.

Dr. Langmead showed (1) a series of congenital malformation of the nose, "fog nose," occurring in members of one family.

(2) Three cases of Mongolian imbecility.

(3) A case of tetany associated with dilatation of the large intestine.

Mr. Keogh Murphy showed:—(1) Cases of tuberculosis of the tarsus, with skiagrams by Mr. A. D. Reid.

(2) A case of ischæmic paralysis.

(3) A case of vesical calculus, with skiagram.

Mr. Arthur Edmunds showed:—(1) A case of spina bifida.

(2) A case of imperforate anus which had been successfully operated upon.

(3) A case of hypospadias.

(4) A case of exostoses of scapula and ribs.

(5) Pathological specimens.

Mr. Mayou showed a case of optic neuritis in one eye, due to retrobulbar inflammation.

Dr. Turtle showed three cases with marked Eustace Smith's murmurs. In one of the cases there were signs of enlarged tubercular gland in the superior mediastinum, with distension of veins over the upper part of the chest, and characteristic cough.

Mr. Laming Evans showed a case of "fragilitas ossium." There had been twelve fractures, involving the right humerus and both femora. There was great deformity of the limbs, and false joints had formed. Skiagrams were shown.

Dr. Willcox showed a case of congenital dislocation of the hip.

The cases were discussed by the President, Sir Wm. Broadbent, Mr. Edred Corner, Mr. Laming Evans, Dr. Guthrie, Dr. Sutherland, Dr. Langmead, Mr. Murphy, Mr. Crisp English, and Dr. Willcox.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, May 10th, 1908.

AT the Laryngological Society of Berlin, Hr. Finder reported on a case of

TUBERCULOSIS OF THE LARYNX AND PREGNANCY.

A woman, æt. 23, had suffered from hoarseness from October, 1905, caused by laryngeal tuberculosis, with ulcer on the posterior wall. Improvement took place under treatment with lactic acid. Pregnancy then supervened, the patient becoming rapidly worse. Artificially abortion was induced. With renewed treatment improvement set in. During the summer of 1906 pregnancy again took place. The improvement, however continued, the ulcer healed, with slight thickening of the posterior wall of the larynx and redness of the vocal cords. In a normal labour the patient gave birth to a healthy and strong child. In October, 1907, the patient became pregnant for the third time, and in January last spontaneous abortion occurred.

A similar case was reported by Hr. Davidson.

Hr. Lenhoff also reported the case of a woman who became pregnant whilst suffering from advanced tuberculosis of both larynx and lungs, and did well at her confinement. To his great surprise, about eight months afterwards the patient again presented herself in a condition of pregnancy, but very ill indeed. The labour passed off normally, but a few months later she had to have tracheotomy performed, her difficulty of breathing being so great. This led to an improvement that lasted several months, but the patient at last succumbed to gradual loss of the vital powers.

THE MORTALITY OF PRUSSIA.

Official statistics have just been published of the mortality in 1906, and, without going into any details, some interesting facts may be gathered. Tuberculosis, notwithstanding its diminishing tendency, caused a considerable proportion of the mortality. Of persons living on January 1st, 1906, 17.26 per 10,000 died of the disease, as against 19.13 in 1905. Inflammation of the lungs caused a mortality nearly as great—viz., 14.14, against 15.45 in 1905. Amongst the deaths from child-bed were included not only the cases immediately fatal, but also those dying from causes connected with it, including puerperal fever, and the death-rate was 1.97, against 2.13 in 1905, whilst the deaths from typhoid fever were only 0.62 and 0.73 in the two years respectively.

As compared with the year 1875, the returns show a very great improvement. The mortality for 1906 was 18 per 1,000, whilst in 1875 it was 26.3. As regards deaths from communicable diseases, the number was less by 16,436 than the previous year.

Twenty-six people died from diseases communicated by animals; there were 4 deaths from rabies, against 12 the previous year, the cause in all the cases being bites by rabid dogs. Anthrax caused 21 deaths—19 males and 2 females—against 18 in 1905. No deaths from trichinosis were announced during the period.

The *Deutsche Med. Zeit.*, No. 31, contains a *résumé* of a paper on the treatment of

INFLAMMATION OF THE MIDDLE EAR,

by Dr. J. F. Neumann. Middle-ear diseases, according to the author, occur *per contiguitatem* from the Eustachian tube; some few, however, are hæmatogenous. The secretion is at first usually sero-mucous. After spontaneous or artificial perforation it becomes purulent from immigration of pus germs either along the tube or through the external meatus; the exudation is purulent from the first only in cases connected with acute infective diseases. At the commencement of a case of acute otitis media, warm moist applications are to be prescribed, compresses soaked in a lotion of liq. plumbi; one should be passed into the ear, the others in front of and behind and over the ear, and all covered with some waterproof material. Cold applications are not so useful, as experiment has shown that inflammations are best combated by warmth. The dressing remains on for twelve hours, and should be continued until either recovery or perforation takes place. The writer has an abhorrence of the Politzer procedure, and also of cleansing the ear with the syringe. The auditory canal should be cleansed by dropping in a 1 to 8 per cent. of a H_2O_2 solution, and the removal of the softened discharge with pledgets of lint. After this a tampon is left in the canal. The tampon consists of absorbent cotton wrapped round a knitting-needle, and smeared over with red precipitate ointment. In place of the ointment-smeared tampon, one may be made use of that has been soaked for 15 minutes in a 1 to 10 per cent. solution of chloretone. Naturally other treatment demanded for other conditions will not be neglected.

AUSTRIA.

Vienna, May 10th, 1908.

NEPHRITIC TUBERCULOSIS.

LICHTENSTEIN presented a young woman, æt. 26, to the members of the Gesellschaft, on whom he had operated for tubercle of the kidney, and from whom he had removed the left. Three years ago she complained of great difficulty in urinating, and later suffered from severe colic, with pain across the whole abdomen. The diagnosis was a corroding destruction of the right kidney, with great enlargement of the left. In operating, both kidneys were exposed, and the left found to be a complete sac of pus, while the right, on the other hand, was normal. This mistake in the diagnosis was due to a crossing of the ureters, which is a very unusual condition.

CUTANEOUS GANGRENE IN HERPES ZOSTER.

Spiegler showed another interesting case of gangrene of the skin, resulting, as he said, from the Röntgen-ray treatment in leucæmia. The eruption on its first appearance was not gangrenous, which showed that the skin was in a healthy condition till the Röntgen rays altered the internal texture and produced an inflammatory process which altered the zoster to a gangrenous condition. Sternberg asked if the patient had been taking arsenic during the treatment. Spiegler replied in the affirmative, and thought that the relationship was between the zoster and the Röntgen rays. Sternberg differed from this opinion, and thought that the herpes zoster was due to the arsenic, which frequently occurs during the treatment of leucocythæmia with arsenic.

ORTHOSTATIC ALBUMINURIA.

Chvostek re-opened the discussion on Stejskal's paper on this subject, which was read last week. Chvostek is of opinion that the orthostatic albuminuria is simply a symptom of different phenomena, the most common of which are diseases in the kidney. He is therefore convinced that this form of albuminuria is nephritic in origin, and the orthostatic a simple type. It is true that orthostatic albuminuria does not always pass on to the severer changes and final destruction, but, like various hypotheses, these are insufficient for any other conclusion.

Loeb attributes orthostatic albuminuria to a particular loss of the coefficient in the cardiac impulse, which leads to a state of decompensation, and produces a functional disturbance in the veins that is fruitful of this form of albuminuria.

Jehle repeated his opinion of lordosis being the sole mechanical factor in the production of orthostatic albuminuria. Pelnack thought that the whole condition depended on the nerve system producing a congestion in the venous circulation of the kidney in the upright position, which may be due to an abnormal change in the motor supply, admitting an overflow into the splanchnic region, and thus producing a distension of the nephritic vessels. In this way oliguria is produced, and it is conceivable that the orthostatic position may also injure the filtering power of the kidney. We must either assume a physical temporary change or a permanent morbid one in the organ. In the upright position the albumin appears; when reclining it disappears. In the healthy individual no change is observed; therefore we must conclude that the filtering function of the kidney is damaged. It is also observed that nervous conditions produce albuminuria, and in certain conditions the nerve system may be disturbed in the recumbent posture or the normal reflex disorganised. It is also observed that this morbid state appears during the lengthening of the long bones, and disappears at puberty, frequently associated with chlorosis and morbid conditions of the genital glands. We have a similar disturbance in the climacteric period, which is only another disturbance of the vascular system. A congested state of the suprarenal bodies may be another source of trouble to the nervous supply of the kidneys.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

DEATH OF DR. TODD THROUGH MOTOR ACCIDENT.—We regret to record the death of Dr. Todd, of Callender, which took place on May 7th, as the result of injuries sustained in a motor accident on the previous day. Dr. Todd was returning from Strathlyn to Callender, when the car swerved and fell over an embankment on the shore of Loch Lubnaig. The other occupants of the motor escaped with trifling bruises, but the car fell on Dr. Todd and caused serious injuries. Deceased had an extensive practice, and was well-known and popular throughout Western Perthshire. He was a widower, and is survived by a grown-up family.

LARBERT ASYLUM SUPERINTENDENTSHIP.—The Stirling District Board of Lunacy met on May 7th, and appointed Dr. R. B. Campbell, M.B., C.M., as Medical Superintendent of Stirling District Asylum, in succession to Dr. G. M. Robertson, who has been elected Superintendent of Morningside. Dr. Campbell is 37 years of age, and held junior asylum appointments at Inverness, Montrose, and Dumfries Asylums, until his promotion about four years ago to the Medical Superintendentship of Inverness Asylum. The other names on the short list for Larbert were Dr. Sturrock and Dr. Rutherford.

DUTIES OF THE EDINBURGH POLICE SURGEONS.—A memorandum has been issued for the information of intending applicants stating that the duties attaching to these offices will be as follows:—To give medical and surgical attendance to members of the police force; to attend daily at the divisional headquarters to see sick and hurt constables; to certify fitness for duty and weekly pay bills as regards numbers of men off duty; to give medical attendance to prisoners in cells of district police stations, and to attend emergencies in the division. The salaries offered vary with the size of the division, from £15 to £80 per annum.

EDINBURGH ROYAL INFIRMARY.—At the last meeting of the managers, a letter was read from Dr. F. W. Haullain intimating his resignation of the post of Assistant Gynæcologist to the institution on the ground that his outside duties made such demands on his time as to render it impossible for him to continue to officiate. The letter was remitted to the medical managers. Though a comparatively young man, Dr. Haullain has for a number of years held one of the largest gynæcological practices in Scotland, and, under ordinary circumstances, the infirmary would have enjoyed the benefit of his services for fifteen years or more. His resignation would be a great loss to the infirmary, and the managers appear to have recognised this in deferring its acceptance meanwhile and remitting the subject to the medical committee. At the same meeting the resignation by Dr. Wade of his position as Assistant Pathologist, owing to his election to an assistant surgeonship at Leith Hospital, was intimated.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—An exensive reconstruction of the premises of the Royal College of Surgeons has been decided upon. The existing buildings will be connected directly with two tenement blocks in Hill Square, which are to be cleared out and rebuilt as laboratories, museum premises, and workshops. A large new hall will be formed on the first floor by building out on either side, the added structure being supported on stone piers. Among other internal structural changes will be the building of a new public staircase to the museum. The works are in the hands of Messrs. Rowand Anderson and Paul, architects, and are estimated to cost several thousand pounds.

BELFAST.

HOSPITAL ABUSE.—The question of hospital abuse in Belfast was raised in the Ulster Medical Society a few months ago by Mr. Fullerton, one of the assistant surgeons to the Royal Victoria Hospital, and, as the result of his efforts, a conjoint meeting of the Ulster Medical Society and the Ulster Branch of the British Medical Association was held, and a committee, consisting chiefly of general practitioners, was appointed to draw up a series of resolutions on the subject. These were printed and circulated, and a meeting of the Ulster Medical Society was summoned to consider them. At this meeting only five members turned up, and it was adjourned for a fortnight. At the adjourned meeting, held on Thursday evening, the 7th inst., the attendance had increased to eleven, including the President and Secretary of the Society. Attention was called to the fact that ten of those present held hospital appointments, while the eleventh was a senior member who had held one in the past. There was not a single representative of the ordinary general practitioner in whose interest the discussion was to take place, and a motion to adjourn the discussion for the present was passed *nem. con.* The resolutions, which have been drawn up with great care, certainly merit discussion, and no doubt they will be considered at the beginning of next session. Meantime, they will be brought up at the annual meeting of the Ulster Branch of the British Medical Association, to be held in Belfast in June. There is a strong feeling among the hospital men that the general practitioners have only themselves to thank for the way in which their patients go off to hospital. If only they would take the small amount of trouble necessary to write a note to the hospital man with each patient they send, it would be far easier to stop unsuitable cases. No doubt there is something to be said on the other side, and among the younger consultants specially there is a great temptation to treat any interesting case without too careful inquiry as to its suitability for hospital. It is abundantly evident to all who have studied the question that it is only by mutual goodwill and good faith between the general practitioner and the hospital man that hospital abuse can be checked.

THE IRISH UNIVERSITY BILL.—The papers continue to print columns of letters upon the University Bill, discussing endless side issues, but generally ignoring the main issue—how University education is to be extended and popularised in Ireland. The General Assembly of the Presbyterian Church in Ireland has met and discussed the Bill, the general result being to show that a large number of the younger clergy of that Church are in favour of it, and many more are convinced that it will become law, and though it does not please them in all particulars, they are prepared to accept it and make the best of it. The Royal University Graduates' Association is still strong in opposition, but this opposition is discounted by the fact that the Association is not a representative Association of Royal University graduates, as its name might seem to imply, but is really an Association got up by the late Dr. McKeown for the express purpose of opposing a local University. As such, the Association is true to its foundation principle in opposing the Bill to the bitter end.

LETTERS TO THE EDITOR.

THE DRINK QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am glad to see your admirable editorial notes to-day on this subject. The abuse of alcohol—drunkenness—as observable in the individual citizen or the nation, is merely a symptom or sign of deep-seated physical, mental and moral diseases, and cannot be effectually dealt with except by treatment of the true efficient causes. In some places where a small percentage of public-houses has been abolished during the past few years the convictions for drunkenness have been diminished, and these events have been placed by some temperance orators in the relation of cause and effect. Such an argument I listened to within the past few days, the speaker illustrating his remarks by the case of Liverpool. It would be impossible to produce a more fallacious argument. During the past thirty years every single measure possible for the social advancement of the people of Liverpool has been promoted on a vast scale. Formerly many thousands of the poor lived in cellars, and many more thousands in overcrowded slum dwellings of the worst description. There was virtually no provision for the isolation of infectious diseases, and none of the beneficial powers of latter-day sanitary legislation had been brought to bear. The speaker also omitted to mention that the tens of thousands of sailors landing in the port from week to week are now effectually protected against the army of male and female reprobates, by whom they were formerly captured, made drunk and plundered. Fine open spaces, magnificent parks, public libraries, art galleries, and every possible civilising influence have been provided within late years, and yet the fanatic can ignore all these factors and ascribe the improvement entirely to the shutting up of a few public-houses. There is no suggestion of abolishing alcohol, and it is evident that slight restriction will be met by provision of more places in another. For example, the mere threat of doing away with grocers' licences has already induced the great houses supplying grocers to open retail shops of their own in many provincial towns. The enormous success of fraudulent quack tonics, the chief ingredient of which is alcohol, suggests another line of supply to the inebriate. The drunkard, as a rule, has no "palate," he cares only for the intoxicating effect of his liquor, and if he can't get vile spirit under the name of gin or whisky he will be satisfied with a concoction of alcohol in one of the forms in which the nostrum-monger may purvey it. Large numbers of women are being insensibly converted into dipsomaniacs by the use of alcoholic mixtures labelled "tonics"; and a vast number of drunkards among women of the "respectable" and well-to-do classes are finding in these "tonics" a means of indulging their morbid appetite without the restraint which the difficulty of secretly obtaining alcohol from the usual sources formerly imposed upon them. Here is a fine field for Government inquiry and interference.

I am, Sir, yours truly,
MEDICAL TEMPERANCE REFORMER.
Liverpool, May 6th, 1908.

MARRIAGE OF THE UNFIT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question of the morality of marriage on the part of persons likely to transmit disease to their offspring is clearly one of the utmost importance to the future of our race. In the case of consumption it would be unsafe, from a medical point of view, for either party to a marriage contract to complete the same while suffering from active tuberculosis. No responsible medical man would sanction such a step. Yet when we come to a no less deadly and disastrous microbial disease, syphilis, we find that marriages are contracted in all grades of society without the least inquiry as to the existence or otherwise of this loathsome malady. So far as the medical profession is concerned, marriage is forbidden in accordance with certain well-defined time limits after the disappearance of all symptoms. But I maintain, Sir, that we should not be content with this passive appeal to medical skill and knowledge. We should impress on the public the duty of parents and guardians to ascertain as far as possible, by careful medical examination, that both parties to a proposed marriage are free from obvious grave disease. In that way it would be possible to eliminate, not only tuberculosis and syphilis, without involving any great personal stigma, but also such conditions as grave organic affections, malaria, diabetes, cancer, and mental unsoundness. There is too much false shame about matters of this kind, and a firm, common-sense handling of them might prevent an immense amount of married misery.

I am, Sir, yours truly,
VERITAS.
Sydenham, S.W.

OBITUARY.

EDWARD HARFORD LLOYD, R.A.M.C.

WE regret to announce the death of Surgeon Lieutenant-Colonel Edward Harford Lloyd, who died on Sunday evening at the Royal Naval Hospital, Chatham. He was on a visit to Fleet Surgeon H. L. Penny at the hospital when he had a heart attack and expired suddenly. He was 72 years of age. He joined the Army as an assistant-surgeon in 1859, was promoted to the rank of surgeon in 1873, and to that of surgeon-major in 1875. He retired in 1885. He served with the Nile expedition in 1884, and was in charge of the field hospital at Kaibar, receiving the medal with clasp and the Khedive's bronze star.

ALEXANDER JOHN BALMANNO SQUIRE, M.B. LOND., M.R.C.S., F.L.S.

WE regret to announce that Mr. A. J. Balmanno Squire died on Thursday last at his residence, 24, Weymouth Street, at the age of 71. Professionally educated at University College Hospital, he became a member of the Royal College of Surgeons, England, and a licentiate of the Society of Apothecaries in 1858, and subsequently took the M.B. degree at London University (gold medallist). He had been house surgeon at University College Hospital, senior surgeon to the British Hospital for Diseases of the Skin, medical officer of St. Marylebone General Dispensary, and lecturer at St. Mary's Hospital Medical School. He was a Fellow of several learned societies, and was the author of several important works on diseases of the skin, amongst which may be mentioned "An Atlas of Coloured Photographs of Diseases of the Skin," "A Manual of Diseases of the Skin," "Treatment of Psoriasis," and "On Lupus." He was the writer of the article on "Skin Diseases in Reynold's System of Medicine."

FREDERICK HOWARD TINKER, J.P., M.R.C.S., L.R.C.P.ED.

WE regret to announce the death of Dr. F. H. Tinker, J.P., who had been for many years a prominent medical practitioner at Hyde, while he was an ex-President respectively of the Ashton and District Medical Association, the Hyde Mechanics' Institution, and the Hyde Division Conservative Association. He was appointed a Justice of the Peace on the formation of the borough bench at Hyde, and was some years ago placed on the Cheshire County Bench.

REVIEWS OF BOOKS.

THE CHEMICAL BASIS OF PHARMACOLOGY.

NO one more than the student of pharmacology deplores the fact that this country is behind in the matter of supplying new synthetic products. The cause of this lies in the fact that little or no atention is paid to chemistry, which, after all, underlies the study of pharmacology and its applications. The chemistry of the various synthetic products introduced into this country by foreign manufacturers is altogether unknown to the practitioner, who, unfortunately, takes little or no interest in the exact composition of the drugs he employs in his practice. Still, the scientific side of medicine can only be developed to its fullest extent when such a knowledge has been acquired. We believe that the volume before us will do much to further such a knowledge. Too long we have been without an English text-book on this all-important subject.

The modes of preparation of the hydro-carbons, together with their properties, form a suitable introductory chapter, in which the methods used in the synthesis of their derivatives are fully discussed. The physiological characteristics of the hydro-carbons are also very fairly considered and commented upon. Alcohols and their derivatives take up considerable space in this work. The aromatic antiseptics, such as creosote, guaiacol, and their derivatives, call for special remark. Substances containing iodine and sulphur include iodoform and ichthyol. Here we find the various substitutes for iodoform, such as europhen and aristol, referred to. The iodides have been largely replaced by such substances as iodalbin and iodipin. The latter is a preparation formed by the addition of iodine to sesame oil. The value of this substance when given subcutaneously has been recently referred to in this country by Burnet in a paper read before the Therapeutical Society. The chemistry of ichthyol has always formed a subject of great interest and speculation. It is an organic sulphur compound of great value medicinally.

The antipyretic series of hydro-carbons is of great interest and importance, and is fully discussed in a special chapter. Their antipyretic action is a function of the benzene nucleus. Recently urea derivatives have been introduced. Of these the best known, perhaps, is veronal. This belongs to the urethane group of hypnotics, which also includes hedonal. The purin derivatives also call for remark.

The chemistry of the alkaloids will be followed with interest by every reader of this work. Three chapters are devoted to their very full consideration. A chapter on local anæsthetics is one of great interest and importance, while the section on glucosids is of considerable value. A chapter on dyes and perfumes concludes the volume.

We have not attempted to criticise the subject-matter of this work, for to do so would have required more space than we have at our disposal. Of course, in a volume such as this, there must be room for criticism, favourable and otherwise; but, on the whole, we are bound to speak of it in terms of the highest praise. In no other English work have we ever found such a full and complete review of the chemistry of drugs. In Germany many such text-books exist, but these are not always available to the English reader; accordingly, the writers of this volume have done well in publishing it. Its need is all the more essential when we find that manufacturers are now disguising the real nature of remedies by adopting short and often meaningless names for them. Thus urotropine is known by at least half a dozen other terms, which only serve to confuse and to mislead the practitioner.

We sincerely trust that this work will serve to awaken an interest in the study of pharmacological chemistry in our medical schools, in many of which we fear that the subject of pharmacology is taught in a very crude fashion. The haphazard use of every new drug is, in these days, a thing to be regretted, and it is only by the careful study of such a work as this that the present-day evils of improper medication can be avoided.

THE OPERATIONS OF SURGERY. (a)

JACOBSON'S "Surgery" has been so long known, and its value has been so much appreciated by successive generations of surgeons and students, that a new edition is always greeted with interest, and one turns eagerly to find what alterations have been made. In the present edition the first feeling is almost one of alarm at the enormous increase in size of the work, the first volume containing over 900 pages and the second over 1,100; and yet, as one thinks of the increased activity in recent years in all departments of surgical work, one cannot be surprised. It will, however, add seriously to the work of those who read this book for the higher examinations. Mr. Jacobson has himself once again undertaken the greater part of the work, but has handed over to Mr. Rowlands the important section of the surgery of the abdomen, whilst Mr. Bellingham Smith has revised the chapters dealing with "Operations on the Ovaries and Uterus." Once again we note with regret the statement that this is the last edition that Mr. Jacobson himself will superintend, and we appreciate sympathetically the pathos of the note that tells us that this was merely undertaken "for the sake of occupation of mind."

Coming now to the work itself, and looking at it in a dispassionate manner, the critic is bound to ask, after a careful examination: Is it a complete and up-to-date representation of operative surgery? Is the increase in size justified? Is the information accurate? In the first place, one has always felt a definite want in the book in the absence of any expression of opinion as to operative *technique*. At one time surgical methods varied so greatly that the exclusion of such a subject was comprehensible; but varying opinions have now been crystallised into methods easily to be classified and only differing in the lesser details; and one would submit that a work which can discuss at length details of diagnosis and methods of examination as questionable as the methylene blue and chloridzin tests of renal efficiency, might well spare a chapter or two to help the beginner to attain a consistent asepsis which is the ultimate fundamental justification for all his surgical activities.

The actual changes in the work necessarily group themselves under the headings of additions and removals. As to the former, modern surgical literature has evidently been thoroughly ransacked, and a vast amount of new material added. Large sections, in places amounting to eight or ten pages, have been transcribed—*e.g.*, that dealing with the plastic surgery of tendons and muscles; single cases of new methods are here and there recorded *in extenso*, with borrowed illustrations; and one cannot but feel that in places the effort to be up-to-date has resulted in the recognition of procedures which will be demonstrated in time to be neither advisable nor harmless. In this connection one misses somewhat that which constituted one of the chief charms of this work in former editions—viz., the author's well-balanced criticism on the methods suggested as the outcome of his extensive personal experience. It is unnecessary to give a list of the various subjects that appear for the first time, but when one indicates, amongst others, that the surgery of the accessory sinuses of the nose, muscle, tendon and nerve grafting, the fixing of fractures by operation, new plans of excision of joints, and of amputations, references to the treatment of various affections by light and X-rays, paraffin injections, etc., it will be obvious that there cannot have been much in the shape of modern progress that has been overlooked.

(a) "The Chemical Basis of Pharmacology: An Introduction to Pharmacodynamics based on the Study of the Carbon Compound." By Francis Francis, D.Sc., Ph.D., Professor of Chemistry, University College, Bristol; and J. M. Fortescue Brickdale, M.A., M.D.Oxon. Physician, Bristol Royal Hospital for Sick Children, &c. London: Edward Arnold. 1908. Price 14s. net.

(a) "The Operations of Surgery." By W. H. A. Jacobson, M.Ch. Oxon., F.R.C.S., Consulting Surgeon to Guy's Hospital, and P. R. Rowlands, M.S.Lond., F.R.C.S., Assistant Surgeon, and Surgeon to the Orthopædic Department, Guy's Hospital, &c. Fifth edition, with 777 illustrations. Two volumes. J. and A. Churchill. Price 42s. net.

As regards elimination, a good deal of old material has been removed; but we cannot help feeling that a still more radical procedure was required here and there. For example, amputation at the hip-joint would never in the present day be undertaken by transfixion, and surely this method, together with Fergusson's old illustrations of it, might with advantage disappear. A similar criticism might well apply to not a few other amputation records; the new is present in most cases, but the old has been also retained. Then, too, there are here and there lists of cases which were of value and interest in days when such proceedings were not common, but which are now comparatively unimportant—*e.g.*, the list of twenty-one cases of nephrolithotomy on pages 188 and 189 of the second volume. The operation is now so common and so successful that these early successes are merely of interest historically. The retention of such things makes the work patchy, and adds much to its bulk.

A special notice must be given of the abdominal section, in that it is the work of Mr. Rowlands. It is a great improvement on the old, and is to a large extent an up-to-date record of modern methods, although here, too, there is an evident desire to retain so much of the old as to render it a little patchy at times. A useful chapter on abdominal aneurysms has been added, but we notice no reference to the method of treatment suggested by D'Arcy Power and Colt. The consideration of hernia is a great improvement. Taxis is merely referred to in the remark that it is important not to waste valuable time over it. In all cases of operation for strangulation one is advised to open the sac, and the old-fashioned method of operation without opening it is omitted for the first time. Gangrenous gut is always to be excised, and, if possible, at once, and the formation of an artificial anus thereby avoided. As to the radical cure of hernia, many of the former methods disappear, and reliance is placed in inguinal hernia on Halstead's, Bassini's and Macewen's methods. As to the intestinal work, one would have gladly seen reference to many of the plans of utilising buttons, bobbins, and artificial appliances of that type omitted, and the surgeon told to depend on the deftness of his own fingers alone. At the present time Murphy's button is merely of historical interest, and the six pages devoted to its consideration might have been saved. Gastric surgery is well represented, but again there are included methods which will probably disappear when further experience of them has been obtained.

Coming finally to the question of illustrations, one would urge the necessity of a much more thorough revision than has yet obtained. There are many excellent modern engravings and wash-drawings, but many of the line drawings are hopelessly antiquated and seriously defective. The whole work is enormously improved, and the amount of information is almost alarmingly extensive. The only fault really to be found is in the direction of imperfect elimination of old and effete material, and doubtless the necessity has merely to be pointed out in order to ensure its accomplishment in one of the many more editions which we heartily trust lie in front of this valuable text-book.

PRACTICAL ANATOMY. (*a*)

WE have great pleasure in welcoming a new edition of Professor Cunningham's Manual of Anatomy. This text-book is so well known and popular in the medical schools that it is not necessary to discuss its merits.

The third edition, published in 1903, possessed many marked improvements compared with the previous issues. The most noticeable feature in it was the many new and excellent illustrations which it contained. In the present, or fourth edition, there are numerous additional figures of the same useful and artistic type throughout the work. Perhaps in this connection those depicting the ligaments round joints may be particularly drawn attention to. The size of the volumes is not materially altered. We notice in Vol. I. that the anatomy of the stomach, especially of its pyloric portion, is dealt with in greater detail. Vol. II. contains a description of the auriculo-ventricular bundle, with an illustration of it, dissected in a calf's heart. The sections through the temporal bone have been omitted in the anatomy of the auditory apparatus, which is a matter for regret.

MANUAL OF SURGERY. (*b*)

THE second volume of this edition of Thomson and Miles' manual, which deals with Regional Surgery, has undergone more alteration and improvements than is to be found in Vol. I., previously reviewed. When first published, in 1904, this part of the work was not nearly so well illustrated as at present. There are 50 additional figures. Well-selected and artistic wood-engravings and diagrams, provided the text is good, as we find here, are an immense help and advantage in studying a subject such as surgery. The volume before us has been increased by one hundred pages. The arrangement of the articles has, in some cases, undergone considerable emendation. There are several new paragraphs, for instance, on lumbar puncture, the exercises for lateral curvature, and the treatment of pruritis ani.

We congratulate the authors for availing themselves so successfully of the opportunities afforded them by the publication of a new edition, to increase the efficiency of their work. The manual can be strongly recommended to the practitioner and student as a well-written and up-to-date text-book of surgery.

INJURIES OF NERVES. (*c*)

MR. SHERREN has been distinctly successful in the treatment of his subject. His book is marked throughout by clearness of thought, careful observation, and critical acumen. With regard to the vexed question of primary union of a divided nerve, *i.e.*, without the occurrence of degeneration in the peripheral end, the author states: "When every case of nerve division is tested carefully before as well as after suture, no more will be heard of primary union." This pronouncement, coming with the *ex cathedrâ* authority of Mr. Sherren, should settle the matter for good. The book merits an unqualified tribute of praise, and is, without doubt, a valuable addition to the somewhat scanty literature of the subject, and should be considered indispensable to every operating surgeon, as well as to the physician who is specially interested in neurology.

(*a*) "Manual of Practical Anatomy." By D. J. Cunningham. M.D. Edin. and Dub., D.Sc., LL.D. St. And. and Glasg., D.C.L.Oxon. F.R.S., Professor of Anatomy in the University of Edinburgh. Vol. I. Upper Limb, Lower Limb, Abdomen. Vol. II, Thorax, Head and Neck. Illustrated with 473 engravings, many in colours. Fourth Edition. Edinburgh and London: Young J. Pentland. 1907.

(*b*) "Manual of Surgery." By Alexis Thomson, F.R.C.S.Ed. Assistant Surgeon, Edinburgh Royal Infirmary; Surgeon to the Deaconess Hospital, Edinburgh; and Alexander Miles, F.R.C.S.Ed., Assistant Surgeon, Edinburgh Royal Infirmary; Surgeon to Leith Hospital. Vol. II, Regional Surgery. Second edition, revised and enlarged, with 203 illustrations, mostly wood engravings. Edinburgh and London: Young J. Pentland. 1907.

(*c*) "Injuries of Nerves and their Treatment." By James Sherren, F.R.C.S. Pp. 310. London: James Nisbet and Co.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

Excretion of Urotropin in the Bile and Pancreatic Juice.—Crowe reports the results (*Johns Hopkins Hosp. Bulletin*, April, 1908, p. 109) of an investigation into the paths of excretion of urotropin from the body. The investigation was undertaken as a result of a suggestion that a biliary antiseptic would prove of great value in the treatment of patients whose gall-bladders contained typhoid bacilli, and the drug hexamethylenamin was selected on account of the fact that it is at present largely used for bacilluria, and is, moreover, easily recognised by chemical tests. The experiments were carried out on dogs and a few observations were also made on patients presenting a biliary fistula. The principal results are summarised as follows:—(1) After its administration by the mouth, urotropin appears in the bile and pancreatic juice of dogs. It finds its way into the bile both through the liver and through the wall of the gall-bladder. (2) It has been demonstrated in the bile, cerebro-spinal fluid, synovial fluid, saliva, pleural effusion, and blood of man. (3) When given in doses of about 75 grains daily, it appears in the bile in quantities which suffice to exercise a decided bactericidal action. M.

Effect of Injected Leucocytes upon the Development of a Tuberculous Lesion.—Opie has succeeded in obtaining large quantities of washed neutrophile cells from the dog by the repeated injection of turpentine into the pleural cavity, and has experimented with them to see if their injection can arrest the progress of a tubercular lesion (*Johns Hopkins Hosp. Bulletin*, April, 1908). An emulsion of tubercle bacilli is first injected into the pleural cavity of a dog, and then an injection of the leucocytes is given. In control animals death occurs in five to six weeks, with marked tuberculosis of the pleural surfaces and of the intrathoracic lymph glands. Injection of approximately 10 c.c's of leucocytes alters materially the clinical course of the disease, as far as dulness on percussion is concerned, but the disappearance may not be permanent. In several instances, however, tuberculous animals which have repeatedly received leucocytes have been found at autopsy to present almost entirely normal pleura and mediastinum, while the control animals showed numerous tubercular nodules and caseous masses.

Hæmatogenesis in Fœtal Sheep.—Goodall has studied the development of the hæmopoietic organs, and hæmatogenesis generally in a series of fœtal sheep, and has arrived at the following interesting conclusions (*Journal of Pathology*, Jan., 1908, p. 191):—(1) In fœtal sheep, measuring from 6 to 1 c.m., hæmatogenesis consists in a proliferation of hæmoglobin—containing megaloblasts in the vessels and connective tissues. (2) The liver is the most important hæmogenetic organ (erythroblastic and leucoblastic) in fœtal life, and no diminution in the activity of its hæmogenetic functions occurs till near the end of intra-uterine life. (3) The thymus lymphocytes are derived from the primitive leucocytes, and not from hypoblastic epithelium. Leucocytes are numerous in the liver and elsewhere before they appear round the thymus epithelium. M.

Epidemic Pneumonia.—Antonine reports the occurrence of acute lobar pneumonia, in an epidemic form, in an infantry regiment, which he had under observation (*Zentralblatt, für Inn. Med.*, No. 15, 1908, p. 368). Out of a total of 600 men 56 were within a short period affected by the disease. During the epidemic certain cases of pneumonic infection of parts other than the lungs occurred, and the author refers especially to one case of acute pneumococcic polyarthritis, and to another of acute middle ear disease complicated with perineal abscess and meningitis. The predisposing cause of the pneumonia appeared to be in most of the cases exposure to cold. The general type of the disease was mild, as all the cases terminated in recovery. M.

Opsonins and Agglutinins.—Sleeswijk (*Annales de l'Institut Pasteur*, December 25th, 1907) publishes a contribution to the study of opsonins more sympathetic with Wright's work than the previous studies emanating from the Pasteur Institute. Up to the present, the workers in the metropolis of bacteriology have been somewhat sceptical of the existence of opsonins as distinct bodies. Sleeswijk, however, by experiments on frogs with the anthrax bacillus, has satisfied himself that opsonins are, at any rate, distinct from agglutinins. On the other hand, he hints that he is in agreement with Levaditi in the view that the normal opsonin is identical with the complement. He states the following as the results of his experiments:—(1) There are in the serum of the frog two bodies (*a*) a substance which prepares the anthrax bacillus for phagocytosis by the phagocytes of the frog; (*b*) a substance which causes agglutination of the anthrax bacillus. (2) Substance (*c*) the opsonin is destroyed by heating at 56° C., while the agglutinin (*b*) is only destroyed at 70° C. (3) The opsonin acts on the bacteria, fixing itself equally on virulent and dead organisms, but not on an indifferent substance such as carmine powder. (4) Lymph and peritoneal exudate have an opsonic power like serum. (5) The phagocytes of frogs may be deprived of their phagocytic power by washing them twice for five minutes in normal salt solution. They may have their power restored by the fresh serum of the frog, while they are left unaffected by warmed serum. R.

The Spirochæte of Yaws.—Castellani describes in detail (*British Medical Journal*, December 23rd, 1907), under the title, *spirochæta pertenuis*, the organism first noted by him in a case of yaws, in 1905. It is an extremely delicate, motile, spiral-shaped organism, varying from a few microns to 20 microns in length. It is stained with difficulty, but good preparations can be obtained either by Leishman's or Giemsa's stain. The number of waves in the body varies, and sometimes part of it is quite straight. Sometimes two spirochætes seem to be twisted together. Castellani thinks he has observed the presence of a flagellum at one end, but requires further investigation to establish the fact. In proof of the spirochæte being the specific cause of yaws, he advances the following facts:—(1) In the non-ulcerated papules, in the spleen, and in the lymphatic glands of yaws patients, as well as of inoculated apes, the *spirochæta pertenuis* is the only organism present, no other being demonstrated either by microscope or culture. (2) The extract of yaws material, containing the spirochæte, but no other organism, is infective to monkeys. (3) The extract of yaws material from which the *spirochæta pertenuis* has been removed by filtration becomes inert. R.

Opsonins and Vaccine Therapy.—The May number of the *Practitioner* is devoted to this subject, and contains articles by Wright and a dozen or more of his disciples. Passing over all question of the utility of vaccine therapy as a settled matter, Wright devotes himself to two practical points—(1) The question whether it is possible to achieve and maintain the desired improvement in the patient's blood apart from periodic blood. (2) The question as to what is the best method of directing such protective agencies as a patient may be possessed of, or acquire by immunisation, to the destruction of the microbes in the focus of infection. In reply to the first question, Wright argues strongly in favour of the advantage gained by regular periodic estimations of the opsonic contents of the blood. Vaccine treatment guided merely by clinical signs is a crude affair, and cannot give the best results. In certain mild or strictly localised infections, however, good results can be got by the use of doses which have been originally determined under opsonic control. On the other hand, in many cases where the course of the disease is difficult to determine, as in most tubercular affections, and in all cases of general septicæmia, clinical symptoms are not to be trusted to furnish the necessary guidance. In the latter class of cases the use of vaccines without opsonic control would appear to be highly risky. On the second point Wright has a very interesting discussion. He holds that in the circulating blood the organism has at its immediate disposal practically the whole of its defensive forces, the phagocytes, and the bacteriotrophic substances existing in the plasma. The object of our treatment, therefore, in all cases of localised infection should be to level up the conditions of the infected tissue to the conditions in the blood. This effect can be best produced by aiding the lymphatic circulation. This can be done in various ways, the old-fashioned remedy of poultices or fomentations being efficacious. In another manner the lymph circulation may be increased by diminishing the coagulability of the blood. This is easily done by the administration of decalcifying agents such as citric acid. Wright recommends 4 grammes three times a day by the mouth, while as a lotion for sinuses and discharging abscesses he suggests 4 parts of common salt and one of citrate of soda in 120 parts of water. Wright's paper is intentionally practical and popular rather than scientific. Fleming contributes a conscientious paper on the accuracy of Wright's method of opsonic determination, and on some of the sources of error. The paper is based on the fullest series of tables which has yet come from St. Mary's Laboratory. He quotes Bullock's observation of the tuberculo-opsonic index in 84 presumably healthy people, where he found that 75 came out with indices between 0.90 and 1.10. In St. Mary's, of 635 estimations in normal sera, 0.8 per cent. were under 0.90, 10.1 per cent. between 0.90 and 0.95, 76 per cent. between 0.95 and 1.05, 10.7 per cent. between 1.05 and 1.10, and 1.7 per cent. over 1.10. Fleming proceeds to point out various sources of error:—(1) With a diminution in the number of washed corpuscles in the opsonic mixture there is an increase in the amount of phagocytosis. (2) Agglutination of the washed red corpuscles increases the amount of phagocytosis. (3) If red corpuscles are taken up with serum the amount of phagocytosis is reduced. (4) Serum sealed in a capsule at room temperature retains its full power, in the case of healthy blood, for at least a week, and, in the case of pathological blood, for a day or two less. (5) Blood capsules left widely open for several hours give very untrustworthy readings. Other conclusions arrived at are:—(1) The tuberculo-opsonic index is the same, whether the washed corpuscles are from a healthy or tuberculous individual. (2) Two practised observers, counting the same slide, obtain results almost always within 10 per cent. (3) Duplicate estimations of the tuberculo-opsonic index of tuberculous patients can be performed, the results differing from each other by less than 20 per cent., except in rare instances.

Wells records certain opsonic estimations on infants under one year old, in relation to various bacteria. He concludes:—(1) A low opsonic index is not diagnostic in children under one year old. (2) In infants a low opsonic index is not inconsistent with health, and a child may be thriving well with a declining index. (3) A low opsonic index rises in response to the stimulus of an inoculation with a bacterial vaccine. (4) The healthy, breast-fed infant possesses no advantage over the healthy artificially-fed child. (5) The anti-bacterial defence in children cannot depend upon the opsonic content of the serum. White contributes a short note in reply to criticisms of the accuracy of the method of opsonic estimation. He shows that in 1906, when his methods were cruder than at present, the experimental error in normal bloods never exceeded 13 per cent. Greenwood, jun., has a very important note on statistical considerations relative to the opsonic index. The discussion is purely statistical. He found, in going over a number of counts of slides, a remarkable unevenness of distribution of the bacilli in the cells, or, in statistical jargon, an excessive "skewness." This, of course, does away, to a great extent, with the value of the average. He concludes:—(1) There is no valid evidence that the limits of error do not exceed 20 per cent. of the mean value. (2) In the case of low emulsions errors in excess are more frequent than errors in defect. (3) There is reason to hope that with high emulsions the variation may become symmetrical. Harris relates some of his experiences in treatment by vaccines. Most interesting are those relating to *B. coli* infections. The conditions treated were infections of the bladder and kidneys, infections of the uterus, colitis. He recommends 5 to 15 millions of bacilli given every two, five or ten days. Inman writes on the value of the opsonic index in the treatment of pulmonary consumption. He believes inoculation, either auto-inoculation or artificial inoculation, an important element in the cure of phthisis. In cases of phthisis not at rest, auto-inoculation is taking place, while in febrile cases rest is essential, and injections of tuberculin under the control of the opsonic estimation are useful. Briscoe and Williams discuss the same subject, with a record of the cases treated. The cases which have done best were those which presented the following conditions: Good physical state, as shown by relation of weight and height; absence of temperature after the first 14 days; pulse below 100; moderately low blood pressure; regular menstruation; a colour index 0.8 or over; red blood corpuscles not less than 4.5 millions per c.m.m.; leucocytes less than 15,000; and an opsonic index tending to remain below normal, and to react sharply to inoculations. The interval between injections was generally 14 days, but in some cases 17. Collier, in a sympathetic note on the relations of surgery to the opsonic methods, closes with a not unnecessary rebuke to the opsonists. "Upon those," he says, "who may intend to follow this specialty, I would urge the importance of wide clinical study, which will enormously add to their usefulness and enable them to escape from the danger of bigotry and the tendency to belittle the efforts of those in other branches of practice." Whitfield, in regard to the treatment of skin affections by vaccines, says that in generalised furunculosis the opsonic method surpasses all others; in early cases of sycosis cure is immediate; in acne the results are variable; in lupus the method is not in competition with the light treatment or ordinary surgical measures. The collection of papers, as a whole, forms a valuable exposition of the results of Wright's methods as practised by enthusiastic disciples. There is an entire absence of hostile criticism. The collection may, therefore, be regarded as an indirect answer to the Johns Hopkins criticisms which we abstracted some months ago. R.

MEDICAL NEWS IN BRIEF

The Irish University Bill.

The past week has brought forward a considerable expression of opinion regarding the Irish University Bill, and most of it can be reduced to the statement that the Bill is not good, but that it is better than none. However, good or bad, it will have received its second reading or else have disappeared before these lines are printed. The preliminary drafts of the charters of the new Colleges were published during the week. The names of the Governing Body of the Cork Colleges have been published, and the names of the Governing Bodies of the Dublin and Galway Colleges have been published as we go to press. We find in the case of the Dublin College the following medical men:—Drs. Denis J.

Coffey (President), M. F. Cox, J. S. McArdle, Alexander Dempsey, George Sigerson, and Sir Christopher Nixon. In the case of the Galway Colleges the following medical men are named:—Drs. Colohan, J. P. Henry, R. J. Kinkead, and J. P. Pye.

A correspondent has already called attention in our columns to the difference between the position of existing professors in the Queen's Colleges, as laid down by Mr. Birrell in his speech introducing the Bill, and as defined in the Bill itself. The question of their position has been raised in Parliament by Mr. Rawlinson, who asked the Secretary of the Treasury what were the maximum terms of superannuation which could be given to professors of Queen's College, Cork, and Queen's College, Galway, under the Irish University Bill; what were the terms of superannuation granted to the professors and officers of the Queen's University in Ireland who were not transferred to equivalent posts in the Royal University of Ireland.

Mr. Hobhouse replied:—"The maximum terms of superannuation—that is to say, pension granted on retirement through age or infirmity—which can be given to the professors under the Irish University Bill are the same as can be given to them now—viz., two-thirds of salary and emoluments, according to the scale laid down by Section 2 of the Superannuation Act of 1859. The maximum terms of compensation, as distinguished from superannuation, are to be determined in each case by the Commissioners appointed under the Bill, subject to an appeal to the Lord Lieutenant in Council. Professors and officers of the Queen's University in Ireland, who were not transferred to equivalent posts in the Royal University of Ireland, were declared entitled to receive by way of retiring pension the full amount of their salaries as officers of the Queen's University, under Section 14 of the University (Ireland) Education Act, 1879."

An important meeting has been held in London of past students of the Queen's College, Cork, for the purpose of considering what action could be taken to secure better treatment for the Queen's College than that foreshadowed in the Bill. The chair was taken by Sir T. J. Galway, K.C.M.G., C.B., who called on Dr. MacNaughton-Jones to make a statement. Dr. MacNaughton-Jones, after referring to the position of the Queen's College in the past, said that Munster was as much entitled to receive a new University as Ulster, and that there was no reason why it should only receive £18,000 while Ulster received £60,000. He considered that the example of Germany showed that population had nothing to do with the matter, as many of its most celebrated Universities were in towns not a third the size of Cork. The two points which they might submit to the Chief Secretary were, first, the utter inadequacy of the proposed grant, and, secondly, the need for greater independence with regard to the internal management.

After some further general discussion, it was decided to ask the Chief Secretary to receive a deputation of graduates and old students of the College.

A Rural Council and Medical Examination of School Children

The following resolution was passed at a meeting of the Rural District Council of Glendale:—"The members of this Council view with extreme disfavour the proposal of the County Education Committee with regard to the medical examination of school children. They consider such a system would entail a large and useless expenditure of ratepayers' money; they think it would be distasteful to very many of the parents; and they are, moreover, of opinion that if Parliament makes such an order, the funds to pay for the working of it should be provided out of the Imperial Exchequer and not out of local rates. They hope that the County Council will not adopt the proposal, and suggest that a strong protest should be sent to Parliament against such a method of legislating."

Dust in Factories.

Mr. Gladstone, M.P., the Home Secretary, received at the Home Office, on May 5th, a deputation, introduced by Mr. Shackleton, M.P., of the executive of the United Textile Factory Workers' Association, who drew his attention to the necessity for an improved exhaust fan for removing dust in the card-rooms, and to the long spell of five hours in bleaching which employers are endeavouring to introduce under a certain provision of the Factory Act of 1878. Mr. Gladstone, in reply, promised to make a close examination as to the hours of work, and to put the matter before the manufacturers. In regard to the dust-removing, he would continue the inquiries. He understood that the fibrous dust was actually dangerous, and had been the cause of permanent injury to health, and discontinuance, consequently, of active work. He asked if the deputation had any figures. Mr. Crinion said he would obtain some. Many young men under 30 years of age had been obliged to give up work through chest troubles. He knew of two cases recently where young operatives had been compelled to go into the workhouse.

Medical Defence Union.

The annual general meeting of the Medical Defence Union will be held on May 21st, at the Medical Institution, Hope Street, Mount Pleasant, Liverpool, at 4.30 p.m. The annual report of the Council, together with the balance-sheet and accounts as certified by the auditors, will be presented to the members, and the usual statutory business as required by the Articles of Association carried out.

Tragic Death of Dr. Gramshaw, of York.

Dr. F. S. Gramshaw, of Bootham, York, was found unconscious in his bedroom on May 5th, and died the next day. The patient's condition up to a late hour on Wednesday, May 6th, gave cause for satisfaction, as during the afternoon Dr. Gramshaw was semi-conscious. Between 11 and 12 o'clock at night, however, pulmonary complications supervened, and from that time Dr. Gramshaw gradually sank. Death is ascribed to exhaustion and collapse, following the effects of the injection of morphia, presumably to induce sleep. The City Coroner had been informed of the occurrence, and an inquest was held on the 8th, when the jury found a verdict of "Suicide during temporary insanity." Dr. Gramshaw, who had practised in York for the past few years, was about 54 years of age. He received his early education at Woodbridge School, Suffolk, and commenced his medical studies at the University College, London, and pursued them later at St. Andrew's University, Dublin and Paris. The deceased gentleman was an extremely able practitioner, and held the following degrees:—M.D., St. Andrew's, 1896; M.D., Pennsylvania, 1871, F.R.C.S. (exam.), 1903; L. and L.M., 1878, L.R.C.P.I., 1885, L.A.H., Dublin, 1873.

Explosion at King's College Medical School.

An explosion occurred on May 8th at King's College Medical School in the Strand, whilst a number of the students were conducting experiments. An experiment was being made with sulphuric acid, when a cylinder burst and injured at least half a dozen of the young men. John Ricketts, who was burnt about the face and eyes, was admitted to the hospital as an in-patient. The others injured were:—Percival Newton, burnt hands and face; Herbert Buxton, burnt hands and face; Walter Harley, burnt hands and face. All are students.

Notes on Books.

We have received from the Editor of the *Chemist and Druggist* a booklet entitled "Dose Tables for Students of Pharmacy." It consists of tables showing the adult doses in ordinary cases of the principal medicinal agents, of the metric equivalents for dispensing, and of atomic weights, comprising the B.P. figures and the International Committee's latest pronouncements ($O = 16$ and $H = 1$). The little book is handy in form and likely to be very useful to those for whom it is intended.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

The following candidates have passed the Third Professional Examination, May, 1908:—W. Coffey, F. J. Colgan, C. H. Christal, W. Crymble, J. Donoghue, T. Duncan, J. Healy, D. J. Harty, F. J. O'Donoghue, P. O'Farrell, E. Ryan, T. Sheedy, P. T. Warren, R. S. White.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

Pur.—The treatment of wounds by heat has been tried two or three times. Verneuille's method consisted in placing the part, thickly wrapped in cotton wool, in a kind of brick oven, and the plan has been somewhat revived by M. Asbeck, another Frenchman, who uses iodoform gauze to wrap the limb in, and a kitchen fire as the means of conveying heat.

Madeira.—The question is more a commercial than a medical one, and we are not clear as to the obligations of the parties. Besides there are points of foreign politics involved, with which we should be very sorry to interfere.

OYSTERS AND INFLUENZA.

The opening sentence of an advertisement in *The Ladies' Field*:—Oysters avoid influenza when eaten regularly.
But they must find it monotonous after the first few times.—*Daily News.*

Anxious.—You will see such a post as you are anxious for in our to-day's advertisement columns. The vacancy is at the Hospital for Sick Children, Great Ormond Street, London, the most important children's hospital in the United Kingdom. The house surgeon receives, in addition to board and residence, a small salary (£20 for six months), but the practice at a hospital of such reputation should be the higher consideration.

Paddington.—We think it would be considered somewhat ungenerous were we to insert your letter in our columns, and manifestly no one could answer your query as to comparative costs. Your second communication will appear in our next.

Besar (India).—Many thanks for your kind letter of appreciation. We can hardly deal with "Dental Surgery" as such without encroaching on the province of the dental journals, but you will frequently find reference to dentisty as affecting the general health and development.

Meetings of the Societies, Lectures, &c.

Wednesday, May 13th.

Society of Tropical Medicine and Hygiene (20, Hanover Square, W.).—8.30 p.m.: Dr. J. P. Maxwell (Amoy): The Use of Quinine during Pregnancy, Labour, and the Puerperium.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. P. Daniel: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. W. H. Clayton-Greene: Abdominal Injuries.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipman); Skin (Dr. Meachen); Eye (Mr. Brooks).

Thursday, May 14th.

Royal Society of Medicine (Obstetrical and Gynæcological Section) (20, Hanover Square, W.).—7.45 p.m.: Paper:—Dr. R. H. Paramore: The Supports of the Female Pelvic Viscera. (N.B.—This paper will not be read, but an abstract will be given, and a discussion will take place, in which leading anatomists and gynæcologists have already promised to take part. Copies of this paper are now ready, and can be obtained from the Secretaries, 20, Hanover Square.) Specimens: Dr. Nepean Longridge: Visceral Hæmorrhages in New-born Infants. Dr. Herbert Williamson: Womb-stone (sent by Dr. Preston Maxwell, China). Mr. J. Bland-Sutton: (1) Two Examples of the Encapsulation of Sterile Fluid in connection with the Fallopian Tubes and the Ovary; (2) Sarcoma of the Uterus. Mr. J. D. Malcolm: A Malignant Ovarian Tumour and Part of a Malignant Sigmoid Flexure removed by Operation.

United Services Medical Society (Royal Army Medical College, Millbank, S.W.).—8.30 p.m.: Lieut.-Colonel A. Duncan, I.M.S. (retired): On the Effects of Heat in the Tropics and their Treatment.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. C. O. Hawthorne: The Diagnosis of Functional Nervous Disease.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); X-Rays. 3 p.m.: Medical In-patient (Dr. Chappel).

Friday, May 15th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Dr. W. J. Horne: Clinique. (Throat.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Cliniques: Surgical Out-patient (Mr. J. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

Appointments.

Carstairs, J. Lindley, M.B., C.M.Glasg., Assistant Obstetric Physician to the Maternity and Women's Hospital, Glasgow.

Chapman, J. S., M.B., B.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Turriff District of the county of Aberdeen.

Johnston, D. J. G., M.B., B.S.Aberd., Assistant Medical Officer of Health of Ipswich.

Mathieson, D. Morley, M.B., Ch.B.Edin., D.P.H., School Medical Officer and Assistant Medical Officer of Health of the City and County of Norwich.

Scott, James, M.B., Ch.B.Edin., Senior House Surgeon at the Bolton Infirmary and Dispensary.

Stamp, William Daniel, M.R.C.S., L.R.C.P., L.M.Edin., Deputy Medical Officer to the Workhouse and Northern District by the Plympton St. Mary (Devon) Board of Guardians.

Stirk, Percy Herbert, L.R.C.P.Lond., M.R.C.S., Medical Inspector of Schools by the Exeter Education Committee.

Wilmot, E. Darwin, M.B., Ch.B.Edin., Junior House Surgeon at the Bolton Infirmary and Dispensary.

Vacancies.

County Borough of Croydon.—Croydon Borough Hospital.—Senior Resident Medical Officer and Bacteriologist. Salary, £160 per annum, with board, lodging, and washing Applications to F. C. Lloyd, Town Clerk, Town Hall, Croydon.

King Edward VII. Sanatorium, Midhurst, Sussex.—Senior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and attendance. Applications to the Hon. Secretary, 19, Devonshire Street, Portland Place, London, W.

Cardiff Infirmary.—Senior Resident Medical Officer. Salary, £120 per annum, with board, washing, and apartments. Applications to Leonard D. Rea, Secretary and General Superintendent.

County Borough of Huddersfield.—Local Education Authority.—School Medical Officer. Salary, £300 per annum. Applications to Dr. S. G. Moore, Medical Officer of Health, Public Health Office, Huddersfield.

The North Riding of Yorkshire Education Committee.—Medical Inspector. Salary, £250 per annum. Applications to J. C. Wrigley, Secretary, Education Offices, County Hall, Northallerton.

City of Edinburgh.—Medical Officer of Health. Salary, £800 per annum. Applications to Thomas Hunter, W.S., Town Clerk, City Chambers, Edinburgh.

West Wales Sanatorium, Alltymynydd, Carmarthenshire.—Medical Superintendent. Salary, £200 per annum, with board and residence. Applications to the Hon. Sec., Dr. Bowen-Jones, Carmarthen.

Nottingham City Asylum.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, etc. Applications to the Medical Superintendent.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications to Stewart Johnson, Secretary. (See Advt.)

Fermanagh County Hospital.—House Surgeon. Salary, £63 per annum. Immediate application to C. Wilson, Secretary. (See Advt.)

Births.

Fraser.—On May 6th, at Trevenna, Slough, the wife of Herbert Fraser, M.R.C.S., L.R.C.P., of a daughter—Joan Mary.

Matthew.—On May 5th, at St. Ives, Cornwall, the wife of F. Crichton Matthew, M.D., F.R.C.S.Edin., of a son

Muriel.—On May 9th, at 109, Scotch Street, Whitehaven, the wife of G. Bertram Muriel, B.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P.Lond., of a daughter.

Osborn.—On May 5th, at Ennismore Lodge, Park Avenue, Dover, the wife of Francis Arthur Osborn, L.R.C.P.Lond., M.R.C.S. Eng., of a daughter.

Thompson.—On May 8th, at Royal Naval Hospital, Great Yarmouth, the wife of Surgeon J. A. Thompson, R.N., of a daughter.

Marriages.

James—Rankin.—On May 5th, at St. Anselm's, Hatch End, Philip William James, M.D., eldest son of the late Canon James, of Bermuda, to Muriel Lindley, youngest daughter of the late A. M. Rankin, of Broomhills, Rochford, Essex.

Vining—Colman.—On May 9th, at St. Matthew's, Ealing Common, Charles Wilfrid Vining, M.B., B.S. (Lond.), third son of R. Willoughby Vining, of 17, Florence Road, Ealing, to Marjorie Gladys, eldest daughter of the late Charles Colman.

Deaths.

Cullingworth.—On May 11th, at 14, Manchester Square, Charles James Cullingworth, M.D., F.R.C.P., Consulting Obstetric Physician, St. Thomas's Hospital, in his 67th year.

Duka.—On May 5th, at Bournemouth, Theodore Duka, M.D., F.R.C.S., Knight of the Iron Crown, Lieut.-Colonel I.M.S., retired, in his 83rd year.

Gramshaw.—On May 7, at 78, Bootham, York, Farbrace Sidney Gramshaw, M.D., F.R.C.S.E., aged 54.

Hoets.—On May 7th, at Sydney, N.S.W., Alton Kingsley Hoets, M.R.C.S.Eng., L.S.A., elder son of the late Rev. I. W. Van Rees Hoets, of 150, Adelaide Road, London, aged 51, of pneumonia. (By cable.)

Knox.—On May 9th, at Church House, Bakewell, Derbyshire, Eliza, wife of John Knox, M.D.

Nutt.—On May 5th, at 5, Northwick Terrace, St. John's Wood, London, Fanny Anne Nutt, widow of William Clarke Nutt, M.R.C.S., late of Plymstock, Devon, aged 86.

Todd.—On May 6th, at Tulipan Lodge, Callendar, Perthshire, N.B., Dr. James Todd, M.D., J.P., in his 70th year

By Appointment to H.M. the King.

Cyllin Inhalant

as given off by the Cyllin Inhalator is most beneficial in all diseases of bacterial origin in the mucous lining of the throat, nose, and ears.

In Influenza

its germicidal action on the specific bacillus situated in the superficial layers of the mucous membrane of the respiratory tract, renders valuable assistance.

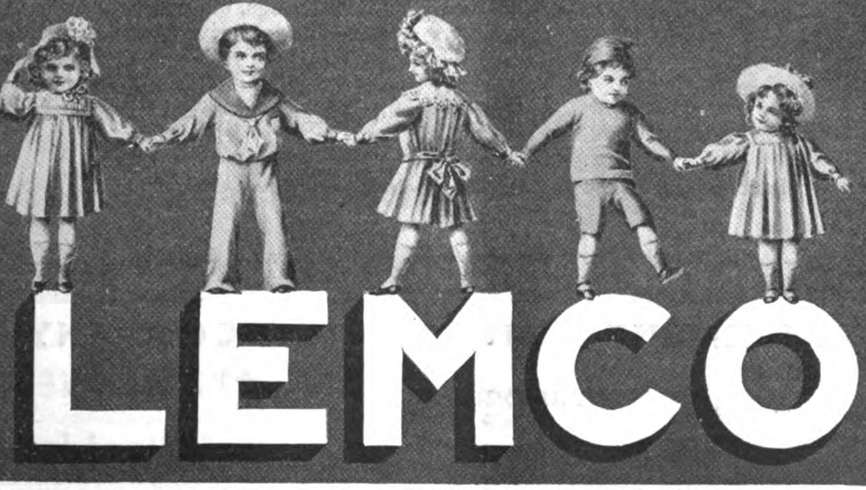
Cyllin is also put up as a Syrup, and in Capsule form (Palatinoids) for stomachic and intestinal antisepsis.

See pamphlet entitled "Standard Chemical Disinfectan's." Copies, together with working samples, sent gratis and post free on applying to

Jeyes' Sanitary Compounds Company, Ltd.,
64, Cannon Street, London, E.C.

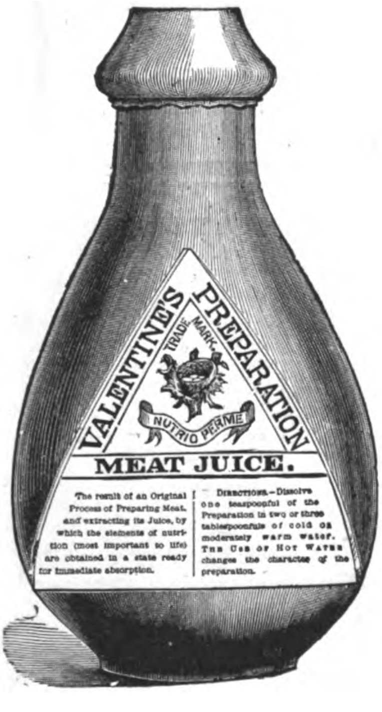
If in doubt-

as to the best food to prescribe to delicate or rickety children, try an eighth or quarter of a teaspoonful of "Lemco" in half a pint of warm milk. Children who cannot digest milk often experience no difficulty with it when combined with "Lemco".



Valentine's Meat-Juice

In **Wasting, Acute** or **Febrile Diseases** of **Children, Marasmus, Rickets, Anaemia, Measles, Cholera Infantum, Diarrhoea,** or **Debility** due to the Immaturity of the Newly-Born, where an Energetic, Concentrated, Easily-Assimilated Nutrient is demanded to Nourish and Sustain, **when milk and other forms of food fail, Valentine's Meat-Juice** is recommended by eminent medical authorities who have thoroughly tested its value in



VALENTINE'S PREPARATION
TRADE MARK
NUTRIO PERME
MEAT JUICE.
The result of an Original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition (most important to life) are obtained in a state ready for immediate absorption.
DIRECTIONS.—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or moderately warm water. THE USE OF HOT WATER changes the character of the preparation.

Hospitals for Children.

Henry N. Read, M. D., *Professor of Diseases of Children, Long Island College Hospital, Brooklyn, N. Y.:* "I have used Valentine's Meat-Juice quite extensively in the Malnutrition and Atrophy of young Children and Babies, and am confident it possesses very valuable qualities."

Prof. Dr. F. La Torre, *Professor of Obstetrics and Clinical Obstetrics, Royal University of Rome, Italy:* "I fed an Infant, which was seven and a half months old, for eight days on Valentine's Meat-Juice, and saw with pleasure the increase in weight of this prematurely-born child, and that its condition was better than it would have been from the use of milk under similar circumstances. I feel confident in saying that Valentine's Meat-Juice is a good, useful, easy food for weak Children, prematurely-born Infants, and for those who have need for special nutrition, as Valentine's Meat-Juice is exceedingly nutritious."

Dr. Raphael Raimondi, *Consulting Physician to the Montmartre Nurseries, Paris, France:* "I use Valentine's Meat-Juice with Nurslings, eighteen months to two years old. Very Weak Babies derive great benefit from the use of this tonic preparation. I give it to Debilitated Infants, after they are eighteen months old, in doses of one teaspoonful in thirty grammes of boiled water twice a day."

Physicians are invited to send for brochures containing clinical reports.

For Sale by European and American Chemists and Druggists.

NOTES AND COMMENTS.

Breakfast Foods.

ONE of the features of latter-day enterprise has been the advertising of breakfast-foods of various kinds, said to be capable of imparting to the eaters all the qualities of Samson and Solomon rolled into one. We confess to having been puzzled as to the necessity for some of these concoctions, both as regards their composition and as to public demand. The Ontario Department of Agriculture has lately issued a bulletin on the subject, prepared by teachers in the Ontario Agricultural College. This document shows that the most nutritious and economical foods are those derived from oats, wheat and other cereals, with a preponderance in favour of oatmeal. As to prepared breakfast foods, says the report, they "are more expensive because of the way they are prepared, the manner they are put on the market, and the cost of advertising. A curious name or appearance, or a mysterious process of preparation does not give them the extraordinary food value sometimes claimed. They may have a place in a hurry-up breakfast; but where economy is considered, there is nothing in the composition, digestibility, or palatability of these high-priced, pre-digested foods to justify the extravagant price asked for some of them." This is good sense and good economics. We only wish our Local Government Board would do similarly good work for us in this benighted country. At present it is sufficient for some speculative advertiser to roll up stale breadcrumbs into pellets, and advertise them as good for the brain, liver, or kidneys, for fond and foolish parents to buy them at exorbitant prices for their children and household.

Damages for Typhoid.

IN March last a case was tried before Mr. Justice Grantham and a special jury, in which the widow of a farm bailiff, engaged at the Three Counties Asylum, in Bedfordshire, sued the Asylums Committee for loss of her husband, alleging that their negligence in supplying impure water for consumption had caused him to contract typhoid fever, which proved fatal. She also complained that he had been provided with improper medical attendance, but happily, this part of the case was abandoned, there being no basis whatever for the charge. After a long trial, the jury, in reply to the judge's questions, found that the husband died of typhoid fever due to the bad state of the water, which was through the defendants' negligence, allowed to be contaminated with sewage. They also assessed the damages at the substantial sum of £650, and expressly exonerated the medical officer from all blame. An appeal against this verdict was made, but on what grounds it is not clear, the allegations that the verdict was against the weight of the evidence, and that the judge misdirected the jury, being exiguous in the extreme. The verdict was upheld by the Court of Appeal, and the case is now closed. This is an exceedingly satisfactory result from the point of view of the water consumer, as there is nothing so likely to rouse water authorities to their responsibilities as the knowledge that these claims can be brought home to them. The academic censure of a Local Government Board Inspector they bear with dignified equanimity, but the fact that their negligence may entail enormous sums in compensation in case of an epidemic is likely to be a potent factor in bringing them to an appreciation of their duties.

Overlying Infants.

THE Children's Bill is making good progress in Committee, and we are glad to see that the Government intend to pass it into law this session. The Under-Secretary for Home Affairs is conducting the Bill in a conciliatory spirit, and there is every reason to hope that a good, workmanlike Act will result; an Act, that is, which will really deal with the evils affecting child-life, and yet not impose impossible conditions on poor parents. A long discussion took place over the clause dealing with the overlying of infants. With regard to the word "overlying" there has been controversy not only in Committee, but in the columns of the *Times*. Mr. Samuel made the interesting announcement that he had referred to Dr. Murray the question of the correct word for the offence, and that that distinguished scholar had, on the whole, pronounced in favour of "overlaying." The letter containing this decision is too long to reproduce, but we are by no means convinced by the arguments adduced by that authority. It is so obvious that the offence is a passive one that the use of the active verb grates both on the ear and on the intellect. However, apart from grammatical considerations, the proposal to make overlying a criminal offence was too strongly opposed for the clause to be pressed, and the question is to be considered anew at a later date. It is certainly beset with difficulties, not the least of which is, that the danger of incurring a penalty may induce mothers to depute the management of the infant at night to others than themselves. Certainly it is desirable that a woman who smothers her baby by overlying when she is drunk should be amenable to severe punishment, and the bulk of the cases would certainly be covered by that provision, but the difficulty would be in getting evidence to prove the drunkenness.

Age and Accident.

AN interesting communication has been made by Sir John Brunner on the relationship of age to liability to accident in industrial pursuits. It is frequently argued that employers hesitate to take on elderly workmen because of the increased risk of accident. The calculations made in the communication referred to deal with the workmen of Messrs. Brunner, Mond, and Co., who have had in employment during the last fifteen years an average of 3,848 workmen. Their experience shows a continuous fall in liability at each age period, the percentage at ages 18 to 25 being 8.5 and that at 56 and over 2.4, the intervening periods showing a uniform decrease from the higher to the lower figure. Unfortunately, the value of these figures is greatly discounted by the fact that all accidents, even the most trivial, are included, and that the numbers actually employed at the various ages is not clearly set out. It may well be that the older men are less liable to minor accidents, but more liable to serious ones; or again that the older men are employed on less risky work; or that the total numbers of old men employed have been comparatively small. Still, the result is significant, as it tends to show that there is not much ground for the *prima facie* assumption usually made that workmen are liable to accident in proportion to their age, and Sir John Brunner is to be thanked for bringing forward the negative evidence so far as he has it to hand.

Natural Method of Healing.

THE methods of the book-tout, though legitimate enough in themselves, lend themselves to much abuse, especially when the operator has to deal with people unaccustomed to his wiles. At Belfast a case has just been tried in the Recorder's Court, which shows the need for caution on the part of nurses who are beset with these gentlemen trying to sell them professional works. It seems that the tout in question invaded a hospital and induced a nurse to promise, or half promise, to buy a book called "Natural Method of Healing," at £1 5s. This volume appears to have been a work by some German quack, and to have been illustrated in a way which his Honour described as "very realistic." The nurse thought it was a text-book of nursing, and signed a paper, on which the Recorder was satisfied the vendor subsequently inserted 3s. as the sum payable per month. When the character of the book was discovered, she sent it back to the publishers, who then sued her for its full price. Happily, the case was dismissed, and the victim did not have to pay the price of her folly. Since our premier newspaper disposed of an enormous number of out-of-date encyclopædias on the instalment system, worthless books have been palmed off on all sorts of unsuspecting people, and the book-lover of to-day cannot take a better motto than *Caveat emptor.*

The Royal Medical Benevolent Fund Society of Ireland.

THE annual general meeting of the Society will be held on Wednesday, June 10th, at the Royal College of Surgeons, at 4.30 p.m.

LEADING ARTICLES.

COSMOPOLITANISM IN MEDICINE.

THE gradual evolution of medical science is in some ways one of the most gratifying results of human endeavour. Year by year medicine is attaining slowly but steadily the firm ground of an exact science. The closest approach to that ideal position has, so far, been made by its subsidiary branch of ophthalmology, but signs are not wanting that in process of time all, or nearly all of the remote recesses of pathology will be effectually explored. So astonishing, indeed, have been the advances already made in the science and art of medicine, that it places no undue tax upon the imagination to conjecture that the secret of life itself may one day be fathomed. Meanwhile, however, there are many gaps in medical knowledge that can be filled only by the patient labour of investigators in all parts of the civilised globe. There is no more striking and interesting fact in this latter connection than the intensity of the modern scientific spirit that fills with enthusiasm the worker in the great fields of medical research. Whatever the accidents of race, language, or geographical position, it is open to the humblest individual at any moment to present a solid and lasting contribution to the sum of the world's knowledge, no matter whether his observation be conducted in a well-equipped European laboratory, in the deserts of Africa, in the swamps of Central America, or in any other likely or unlikely quarter of the world. In a word, medical research is essentially cosmopolitan in its nature, and every addition to its store of achievement represents so much gain to the world's commonwealth. But the greater diffusion of scientific labour has necessitated a better machinery for the interchange of observations. A good example of this extension of international interest is afforded by the vast number of English medical books which are sent every year to American readers, and *vice versâ.* To a less extent a demand exists for medical books between all civilised countries. There are a few international medical journals, but these are limited, almost of necessity, to nations speaking a common language. Of late years the circulation of medical journals in colonies and in English speaking countries has undergone a great expansion. In the case of British colonies and dependencies, there has been a large and steady increase of the demand for home journals. In our own case, we have been able to register a gratifying increase of circulation in America, Canada, South Africa, India, and Australia, not to mention such places as Japan and the West Indies. We have no doubt that the experience of THE MEDICAL PRESS AND CIRCULAR has been shared by other leading medical journals in the United Kingdom. One marked feature in the journalistic literature of to-day is the prominence of abstracts and short notes. Some of the most valuable parts of a medical practitioner's education is picked up from chance suggestions of that kind. Moreover, there is often a freshness and attractiveness of form about information that hails from another country which is not altogether easy to explain. Some day a scientific Volapuk may be introduced as the medium for interchange of the world's opinions. We have already arrived at the stage of international medical congresses of various kinds. On the whole, this cosmopolitanism of medical work is a thing to be carefully fostered. Should mankind ever be blessed with the Millennium, its advent will probably be in no small degree rendered possible by the influence of cosmopolitan and humanising medical science.

HOUSING LAW AND THE BIRTH RATE.

For some years the outstanding feature of the Annual Report of the Registrar-General on Births, Marriages and Deaths has been the steady decline in the birth-rate. It is hardly possible to overrate the significance of this fact, whether it be viewed from the social, the economic, or the Imperial standpoint. History has shown that one of the first signs of decadence is a fall in the ratio of increase of population. In France, at the present moment, so great has been the diminution in that respect that the question has been seriously mooted as to whence the next generation will draw its soldiers. Since the days of Malthus the problem of the relation of the population to the status of the nation has been ever before the thinking reformer and politician. In the United Kingdom, imbued as it is with an underlying spirit of puritan morality, the matter has given rise to the keenest controversy. In spite of all protest, however, the fact remains that our national birth-rate has fallen to a point well-nigh unprecedented. The decrease, moreover, has been due to the limitation of families amongst the upper and middle classes. In the process of time the movement according to the usual social experience, will spread to the poorer classes, and thus sooner or later the crux of the question will be forced upon the attention of the legislature. In discussing the matter broadly, one of the first things to be noted is the way in which the State has for generations past successfully increased the average duration of life by the adoption of many wise sanitary laws. In this way the diminished rate of production is appreciably counteracted by the longer life-value of the product. Another phase of a kindred nature is the movement now on foot to reduce the excessive infantile mortality. It needs no formal argument to show that the diminished output of children will be counterbalanced if a proportionately greater number can attain healthy adult life. From that point of view all enlightened schemes of national health advancement acquire a significance deeper than that which has hitherto invested the labours of the sanitarian. The most recent advance of the kind is embodied in the new Housing Bill now being brought forward in the House of Commons by Mr. John Burns. Its main object, to put the matter in a nutshell, is to do away with slums in town and country. The housing problem has been strained to the uttermost in the towns by the steady exodus which has decreased the rural population of England by fifty per cent. or more. But the need for stringent legislation with regard to housing is hardly less urgent in the country. Mr. Burns proposes to bestow compulsory powers of acquiring property upon local authorities. It compels the owner of small properties to keep his houses in a condition fit for human habitation. It confers upon the Local Government Board the right to take action should the local authorities evade their responsibility. Beyond a doubt, this measure registers a reform in national sanitation of first importance to the future of the race. It is to be hoped that all British Colonies and independencies will follow the example set by the Mother country. In younger communities it is often easier to adopt new principles than is the case where more complex and old-standing interests are involved. In any case, an honest endeavour to improve the housing of a number may be hailed as a step in the right direction towards the attainment of the ideal in the Commonwealth of mankind.

CURRENT TOPICS.

The Society of Members and the Council of the Royal College of Surgeons.

At a meeting of the Council of the Royal College of Surgeons of England held on Thursday last, the President reported the steps which he had taken with regard to the proceedings of certain members of the College in connection with the poll of Fellows and Members on the admission of women to the examination for the diplomas of the College. The proceedings of the President were approved and confirmed. In his report the President stated that in deciding to take notice of the unofficial circular, which had been issued by the Society of Members, he was desirous of securing the object aimed at by the Council, of obtaining simple and direct answers to the questions in the ballot paper. He also stated that he was further influenced by the following considerations:—

"While, apart from the question of propriety, it may be open to any member or group of members to take an unofficial poll in such form as they may think fit, it was, in my opinion, improper that the members in question, not content with taking a poll, introduced an issue which intentionally had not been placed before the members by the Council. The Council would remember that in May, 1907, it was resolved 'that in the event of women being admitted to examination, all diplomas granted to them would be granted by virtue of, and subject to the Act of 1876, in order to make it clear that women acquire no right to take any part in the government, management, or proceedings of the College,' and the terms of the official circular make it clear that the questions put by the Council relate to the admission of women under existing powers conferred by the Act of 1876. The suggestion in the unofficial circular, that affirmative answers to the Council's questions should be in the form of 'Yes, with full Collegiate rights,' is a suggestion that women should be admitted not under existing powers, but under powers which the Council might or might not be able to obtain in the form of a new Charter, and this seeks to introduce an issue which the Council have not placed before the members."

"It is, moreover, obvious that difficulty must arise with regard to the meaning of answers in the form suggested by the unofficial circular. Some members so answering may mean that they are in favour of the admission of women under any conditions, but preferably with full Collegiate rights, whilst others may mean that they are not in favour of women being admitted unless full Collegiate rights be granted to them. In taking the result of the poll the question will therefore arise as to whether such answers can be regarded as valid." To us it seems a pity that the Society of Members, which has done so much good work for general practitioners, should have suggested the action they did, as it has merely irritated the Council of the College and apparently made them more hostile to members' claims, and has not advanced the cause they had at heart.

Medical Inspection of Children in Canada and America.

Among the many functions which the school doctor should perform, and which under the present proposals of the Education Board he will be unable to carry out efficiently, is that of recognising and taking early action with regard to infectious diseases. We note with interest that Dr. Laberge, Chief of the Staff of Medical Inspectors of Montreal, reports that there has been a fall of no less than 50 per cent. in the notification of infectious diseases in that city since the introduction of school inspection by medical men. This result he attributes to the increased cleanliness of children, to better ventilation, and to the prompt checking of outbreaks as the result of frequent inspection; a condition of things that the rare appearances of inspectors as at present proposed in this country, would not be calculated to effect. Medical inspection has not only been adopted in Montreal and Toronto, but even in some of the small Western townships; the first district in Canada which instituted the system being Pincher Creek, Alberta. In the United States inspection, which was adopted by Chicago some time ago, but discontinued, had been revived to the general satisfaction of parents, who were frightened by a series of scarlet fever outbreaks last year. Here too the doctor goes to the schools under his charge every morning, and examines any children who are suspected of infectious disease or have been absent for more than four days from any cause. As a matter of fact each doctor is assigned only three or four schools, containing altogether three or four thousand children, but he is expected thoroughly to do his work, seeing the absent children, if need be, in their homes. Whatever the difficulties of such a plan may be, it is obvious that it is far more likely to be effectual than the three or four "inspections" during school life that our own Education Board favours.

Tuberculosis in Ireland.

The opening of the Tuberculosis Exhibition, organised under the auspices of her Excellency the Countess of Aberdeen, marks a departure that may well prove an example to the rest of the world. The chief speaker on that occasion was General Sir William Butler, who gave a stirring address. His arguments were based upon the "one awful fact" that within one year 12,000 of their fellow-countrymen had died from tuberculosis, a disease that was preventible under proper conditions as to air, food, and general environment. The general feeling of the movement was registered in the following resolutions, which were carried unanimously:—(1) "That special registration should be introduced without delay with the object of making it compulsory that all cases of pulmonary tuberculosis should be notified, taking care at the same time to protect consumptive patients from any undue interference with their liberty." (2) "That the adoption of more stringent and uniform measures for the regulation of milk and food supplies is urgently required." (3) "That County Councils in Ireland should be enabled to erect and maintain such hospitals, sanatoria, and dispensaries for the treatment of consumption as they think fit." (4) "That there is urgent necessity for a system of medical inspection of schools and school-children."

An Official Directory of Nurses.

We do not know that anyone will regret the fate of the ill-judged Bill introduced by Lord Balfour last week to the House of Lords. It was properly pointed out in criticism of the measure that the proposer had not been able to adduce a single medical corporation supporting the Bill. The working of the Midwives Act has not been such as to encourage us to take any step toward giving nursing a quasi-official status as a profession; but, whatever might be said in favour of State registration, we know nothing to justify an official directory. For admission to a State register presumably certain requirements of education and training would be necessary, whereas a directory—official or otherwise—would be merely an untrustworthy list of those engaged in the occupation of nursing. Registration might be compulsory—enrolment in a directory would be optional. A directory would, therefore, fulfil no useful purpose. Incomplete, and at the same time also indecisive, it would be useless even as a work of reference, whereas admission to its pages would doubtless be claimed by nurses as proof of official status.

Medical Men and Academic Management.

A considerable amount of hostile criticism has been roused by the prominent position accorded to medical men in the governing bodies of the new University and College to be founded in Ireland under Mr. Birrell's scheme. It is claimed that the medical profession has a considerable over-representation as compared with other professions; there are, for instance, some dozen medical men on the proposed Senate, whereas there are but two lawyers. The comparison, however, is hardly a fair one. The medical men are to be regarded as representative, not merely of medicine, but of science, and many of them are engaged in purely scientific work. Lawyers do not in any analogous fashion represent any special sphere of academic study. Moreover, if judged merely as professions, there is no doubt that, for the present, at any rate, it is more important to have medical men than members of other professions in positions of influence in the new University, for among the professional schools the medical school will be the most frequented. It is possible that in the future, schools of commerce, or industry, or agriculture will predominate, but under present conditions it is certain that medical students will be more numerous. Mr. Birrell was right, therefore, in the interests of both science and medicine, in finding place for a considerable number of medical men on the Senate. It is a point of interest that when the new scheme is carried out, the heads of three of the five Colleges of University rank in Ireland will be medical men, viz., Dr. Traill, of Trinity College; Dr. Winder, of Cork; and Dr. Coffey, of the new College in Dublin; while the head of the Galway College, though not a medical man, is a teacher of science.

The Position of the Royal College of Surgeons in Ireland.

A very strong case was made on behalf of the Royal College of Surgeons in Ireland during the second reading debate on the Irish Universities Bill, both directly and indirectly. Mr. Campbell, the late Attorney-General for Ireland, speaking as the representative of what "might be considered a rival of the College School, declared that the worst blot upon the Bill was the gross injustice it tried to perpetrate upon the College School. It would be a great injustice on the part of the State, which he thought that House would never tolerate when they realised it, to crush a School such as this, which had been in existence for over a century and a half, for the benefit of its rival." Again, Mr. Kettle, expressing the Nationalist view, declared that "nobody wanted to inflict any injury on the College of Surgeons—it obviously had a case." Lastly, Mr. Haldane said, although his words did not refer to the College School, that, in his view, "it was a mistake to meddle with existing institutions in Ireland. You want to add to them, not to destroy them." The Council of the Royal College of Surgeons asks for a grant of money for the purpose of endowing certain of its chairs, of establishing prizes and bursaries for poor students, and of maintaining the School in the highest state of efficiency, so that it may be in a similar position to its new rival. Mr. Birrell, in his reply, did not mention the College School, and we trust that his silence indicates that he is preparing to re-consider his attitude towards the College. It would be strange if one who by nature is so strong an opponent of denominationalism in education should be even indirectly responsible for the destruction of what, if everyone is to be believed, will be the only undenominational medical school in Ireland.

PERSONAL.

Principal Donald MacAlister will preside at the 87th Session of the General Medical Council on May 26th, at 2 o'clock.

Dr. J. S. Mather has been made the recipient of a clock by the Bristol Branch of the Midland Railway Corps of the St. John's Ambulance Association.

Dr. S. G. Scott, on retiring from the Demonstratorship of Physiology at Leeds University, has been entertained at a complimentary banquet by the Leeds Pathological Club.

Dr. Henry, who has been Medical Officer of Rochdale for nearly 29 years, has been offered the position of whole time Medical Officer for the borough at a salary of £600 per annum.

Inspector-General of Hospitals and Fleets, Sir Herbert M. Ellis, K.C.B., Director-General of the Naval Medical Department, has been placed on the retired list at his own request.

Sir William Smyly, M.D., has been nominated as President of the Irish Medical Association for the coming year.

Dr. J. Walton Browne, M.D., and Dr. R. W. Leslie, M.D., have been elected representatives of Convocation on the Senate of the Royal University of Ireland.

Sir William Allchin will open the Summer Post-Graduate Session of the Mount Vernon Hospital for Consumption with a lecture on "Some Inter-Relations of Thoracic and Abdominal Disease."

Sir William B. Berry, M.D., has been granted the Royal permission to retain the title of "Honourable" on retiring from the Speakership of the House of Assembly of the Cape of Good Hope.

Dr. Alexander Granville has received the King's licence and authority to wear the Insignia of the Fourth-Class Order of Medjidieh conferred on him by the Khedive in recognition of distinguished service.

We regret to learn that Drs. Raikes and Wray, Government medical officers, have died of plague, which they contracted while performing a post-mortem examination on a patient who died while in quarantine.

The members of the "Loyal Hall of Justice" Lodge of Oddfellows, Steyning, have presented Dr. Charnock Smith with a handsome illuminated address, appropriately voicing their genuine regret at his coming departure.

The Murchison Scholarship, awarded alternately by the Royal College of Physicians of London and the University of Edinburgh, has been won by Mr. E. L. M. Lobb, of Guy's Hospital. This scholarship was founded in 1880 to commemorate the work of Dr. Charles Murchison.

Dr. L. F. Barker, Professor of Medicine in Johns Hopkins University, Baltimore, and formerly of the University of Toronto, was honoured by Queen's University, Kingston, on April 29th, by having conferred on him the honorary degree of Doctor of Laws.

Mr. Charles J. Heath, F.R.C.S., one of the surgeons of the Hospital for Diseases of the Throat, Golden Square, London, has generously given a donation of £250 to the hospital for the purpose of increasing the number of beds and thus reducing the existing delays in the performance of operations.

A memoir of Dr. Edmund Symes-Thompson, Gresham Professor of Medicine, whose death was recently reported in these columns, has been prepared by his widow, and will be shortly published by Mr. Elliot Stock. Lord Balfour of Burleigh is a contributor to the volume, which will also contain a portrait of Dr. Symes-Thompson.

As a testimonial of the great work of Dr. Walter B. Geikie, formerly Dean of Trinity Medical College, in advancing medical education in Toronto, and in founding and building up Trinity Medical College, his life-size portrait in oil was unveiled before the Academy of Medicine, on Tuesday evening, April 7th, in the presence of a large number of Fellows of the Academy and friends. The picture was accepted by Dr. Geikie and presented by him to the Academy of Medicine.

A CLINICAL LECTURE
ON
THE AFTER-RESULTS OF THE SURGICAL TREATMENT OF UTERINE DISPLACEMENTS. (*a*)

By ARTHUR E. GILES, M.D., B.Sc., F.R.C.S.,

Surgeon to the Chelsea Hospital for Women, and Gynæcologist to the Prince of Wales's General Hospital, Tottenham.

THE surgical treatment of uterine displacements depends upon results for its justification. Other conditions, such as tumours, are in themselves sufficient indication for operation, whatever the remote results may be; but with displacements, if operations for their relief do not relieve, or if they create more serious troubles than they cure, they must give place to other methods of treatment.

I have, therefore, inquired into the after-results of my operations for displacements. These operations can be classed in three groups. In the first, the uterus was suspended to the abdominal wall, with or without the addition of plastic procedures on the vaginal walls. In the second group, the uterus was suspended, and the appendages of one side were removed on account of a tumour, inflammatory disease, or tubal pregnancy. In the third group, the uterus was suspended, and one or more fibroids removed from its walls.

Some of the cases operated upon are too recent for records of after-results to be of much value—those, namely, in which the operation was less than a year ago. Of the remainder, some could not be traced owing to removals. The material at my disposal is as follows:—

Group.	Operation.	Total Cases.	Cases operated on a year or more.	After-results investigated.
1	Hysteropexy	160	130	93
2	Hysteropexy and unilateral Salpingo-oöphorectomy	48	37	32
3	Hysteropexy and Myomectomy	19	13	11
		227	180	136

In a paper read at the British Medical Association meeting at Toronto in 1906 (*b*) I dealt with the subject of Hysteropexy or Ventrofixation from the point of view of indications for the operation, technique, and after-results. In this communication I do not propose to touch on either indications or technique, otherwise than incidentally; but I wish to amplify what I then said on the subject of after-results. At the present date I have performed 80 more operations than I had then, and the cases in which after-results have been traced have been increased from 73 to 136.

Just a word may be said on the subject of nomenclature. In this country the term "ventrofixation" has been applied generally to all cases in which the uterus is attached to the abdominal wall; the term "ventrosuspension" has been employed almost interchangeably. But in the United States and the Colonies a sharp distinction is drawn between the two terms. By ventrofixation is understood an operation in which the uterus is made to assume a position of extreme anteflexion, and the sutures are passed through its posterior wall and firmly fixed to the fascia. A normal pregnancy after such an operation is practically out of the question. By ventrosuspension, on the other hand, is meant an operation in which the sutures are passed through the anterior wall of the uterus or the fundus, and tied to the peritoneum, and not to the fascia. By this means any subsequent pregnancy can develop undisturbed, but there is a definite tendency to return of the displacement owing to the ease with which the peritoneum stretches. The operation that I have almost invariably adopted differs from both of these, in that the sutures are passed through the anterior wall of the uterus, low down, leaving the fundus free in the event of subsequent pregnancy; and these sutures are passed on each side of the incision through the fascia as well as the peritoneum, so as to guard against a return of the displacement. Therefore, to avoid confusion, I have decided to abandon both the above terms, and use the word "hysteropexy," which merely implies that the uterus is stitched up to the anterior abdominal wall.

In order that we may claim to have cured displacements by surgical means, it must be shown that certain requirements have been fulfilled. These are:—

(1) The patient's general health subsequent to operation must be satisfactory, in so far as the operative results are concerned.

(2) The displaced organs must remain in good position.

(3) The necessity for pessaries must be done away with.

(4) There must be no interference with the bladder.

(5) It must be possible for normal pregnancy and labour to occur, and for the good position of the organs to continue undisturbed.

(6) There must be no trouble resulting from the abdominal scar.

In a review of a book by Dr. Casalis, of Wynberg, in the *British Medical Journal* of March 7th, 1908, the reviewer says:—"There are manifest objections to all kinds of fixation operations, and at the best it is not easy to define what can conscientiously be registered as a 'cure.'" I think that any case that fulfils the above requirements comes within the definition of a cure, and can be conscientiously registered as such. I shall now present my report of after-results under the six headings just enumerated, and we shall then be able to decide how far we are justified in saying that these patients have been cured.

(1) *General Health.*—It is obvious that we cannot expect to cure such conditions as chronic indigestion, anæmia, epilepsy, lung troubles, etc., by operations on the pelvic organs, and the fact that patients who have suffered from such conditions continue to do so cannot be regarded as invalidating the operations. Conditions of general health for which the operation may be considered responsible are general debility and neuroses, coming on subsequent to the operation, and pain referred to the pelvic organs.

Of the 136 cases, 5 felt better until pregnancy or confinement occurred, and had felt weaker or not so well since; 3 had felt much better until within the last month or two; 4 had suffered from various troubles—namely, gastric ulcer, hæmorrhage after miscarriage, curetting and fistulæ in ano; 1 had had a subsequent hysterectomy for uterine fibrosis; 1 was reported by her doctor to be a "hopeless neurasthenic"; 9 stated that they were about the same as before the operation, and in 2 of these this fact was accounted for by a return of the displacement; and 9 stated that they felt weaker or otherwise worse.

The remaining 104 felt better than before the operation, although some of them had not very good health on various accounts. Many of them described their improvement in such terms as "perfectly well in every way since the operation"; "much better than before"; "better than for years"; "a world better—I was no good only to lie on my back and suffer"; "better than ever I have been"; "decidedly better in every way"; "I was very glad to do away with pessaries";

(*a*) An Address delivered before the Tottenham Division of the British Medical Association.

(*b*) A study of 146 consecutive cases of Ventrofixation of the Uterus, *Brit. Med. Journ.*, Nov. 3rd, 1906.

"a lot better—not like the same person"; "a different woman altogether"; "I'm twice the woman I was"; "very different to what I have ever been for years before the operation"; "better—no comparison." I have given the patients' own words, because they convey a much better idea than any statistics. Properly, we must include in the cases of improvement those who were better until some extraneous condition supervened, and we may therefore say that, of the 136 patients, 116, or 85 per cent., were decidedly improved in their general health; 10, or 7½ per cent., remained about the same; and 10, or 7½ per cent., were worse.

(2) *The Position of the Pelvic Organs.*—One case requires to be excluded, as a hysterectomy was done subsequently. Two patients were not seen, as one is in Jamaica and the other in South Africa. In 4 cases the uterus was in good position when last examined, but the patients have since been confined, and I have no report of the position of the organs after the confinement. In 6 cases the uterus was mobile, or presented a slight degree of retroversion, apparently owing to lengthening of the "attachment band" which sometimes forms; one of these patients had been confined. In 14 cases there was some relaxation of the vaginal walls or deficiency of the perinæum; two of these had been confined. In 4 cases the operation was a failure, as the uterus became detached from the abdominal wall, leading to a return of retroversion in 2 of them, to prolapse in 1, and total procidentia in the fourth. I hope to operate again shortly on the last case. The other three were re-fixed, and the result remained good. The four unsuccessful cases were operated upon in May, July, and September, 1904, and in November, 1905. The first three were due to insufficiently secure fixation; the last case was a very stout woman with lax tissues. After 1904 I generally employed three sutures to secure the uterus, instead of two, as I often used before, and there have been no failures in the later cases.

As far as the results of the hysteropexy were concerned, we find that, excluding the first 7 cases mentioned, there were in all 129 cases, in 119 of which (92 per cent.) the uterus remained firmly fixed to the abdominal wall; in 6 (5 per cent.) the uterus was suspended by a band; whilst in 4 (3 per cent.) the operation failed.

It has been said that, while hysteropexy gives good results when done for retroversion, it is unsatisfactory in cases of prolapse and procidentia. This has not been my experience. Of the 119 cases examined, 97 were done for retroversion, 2 of which were failures, as above-mentioned; 21 were done for prolapse, and these were all successful; 10 were done for procidentia, in 1 of which the procidentia returned completely, whilst in the other there was a partial return—viz., to the stage of prolapse. In a certain number of cases a plastic operation was done on the vaginal walls; referring only to the 119 cases examined, a perinorrhaphy was done in 29 cases; in 21 of these the perinæum remained quite sound; in 8 the perinæum was found stretched, a confinement having occurred in 2 of them; and in 1 case, where confinement had also taken place, the perinæum had torn again. An anterior colporrhaphy was done in 7 cases; in 4 of these the anterior vaginal wall remained good and taut; in 2 there was a partial, and in 1 there was a complete return of cystocele. More or less prolapse of the vaginal walls was present in a certain number of cases where no plastic operation had been done. My criticism of these cases is that results would have been better if I had done more at the time of operation. Of later years I have done more combined operations.

(3) *The Necessity for Pessaries.*—I have not precise records on this point. In only 3 cases is there any note that a pessary was required after the operation, and I think that I shall be well within the mark if I say that not more than half-a-dozen patients have had occasion to wear one. We are, therefore, I think, justified in saying that surgical treatment for displacements obviates the necessity for pessaries.

(4) *Interference with the Bladder.*—It might be supposed that trouble would generally arise from the fact that the attachment of the uterus to the anterior abdominal wall prevents the ordinary expansion upwards of the bladder as it becomes fuller. I therefore made special inquiry as to bladder disturbance after the operation, and my reports give particulars of 125 cases. In 85 of these the patient had no trouble at all with the bladder; in 2 there was frequency of micturition, but it was less troublesome than before operation; in 5 there was frequency, about the same as before the operation; 1 had frequent micturition for six months, and 1 for a year after operation; 6 had frequent micturition sometimes; 2 complained of it during or after menstruation; and 12 complained of habitual frequency; 1 patient had frequent and painful micturition; 5 had pain during or after micturition; 2 had pain when they held the water too long; and 3 had difficulty in passing water at times. Summing up, we find that 92 either had no trouble or had no more than before; while 21 complained of frequency, and 12 of pain or difficulty. In percentages, 74 per cent. had no trouble, or none more than they had before; 17 per cent. had frequency, and 9 per cent. had pain or difficulty. If we investigated the matter in relation to patients who had not had a hysteropexy done, I think that we should still find as large a percentage of women who had either frequency or pain; and therefore the operation cannot be regarded as presenting any serious drawback from this point of view.

(5) *Pregnancy and Labour after Hysteropexy.*—I have not infrequently been asked by medical men who have seen me doing these operations: "But what happens if the patient should become pregnant?" And I have replied: "Well, it would be all right, because the attachment is done in such a way as to leave the fundus free to expand." It now remains for me to justify this statement.

Thirty-four patients became pregnant after the operation; 1 of them had 3 pregnancies, and 4 others had 2 each, making in all 40 pregnancies. Of these, 4 were pregnant when last seen, whilst 36 had terminated. Of the completed pregnancies, 10 ended in miscarriages at periods varying from 2 to 5½ months, and 26 went to full time.

With regard to the miscarriages, it may be noted that no fewer than 6 took place within a few months of the operation, and I think that it may fairly be urged that pregnancy was allowed too soon. Two of these patients had a normal confinement afterwards; 1 patient had had 4 or 5 miscarriages at 2 to 3 months before the operation; afterwards she became pregnant, and indulged excessively in dancing, with the result that she miscarried at 4 months; 1 patient miscarried at 5½ months, by which time the uterus had probably enlarged beyond the stage of being affected by the operation; and 1 patient miscarried after she had had two full-time pregnancies, so that it was independent of the operation. When we take into further consideration the fact that among women who have not had the operation of hysteropexy the proportion of miscarriages is about 1 in 4, we can justly conclude that the operation can be held responsible for miscarriages in only a small percentage of cases.

Turning to the cases of confinement of living children, 19 were reported as quite normal, some of them being also described as easy and rapid. One of these I had the opportunity of attending myself, in a primipara, æt. 37; the labour was absolutely normal, and the second stage was completed in about an hour. One patient was confined twice at 7 months, the presentation being in each case a cross-birth. She stated that precisely the same thing happened in a confinement which took place before the operation. In two cases forceps were required for occipito-posterior presentations; in two others forceps were required for "delay," and in one there was said to be a "rigid cervix," for which forceps were used. These results compare very favourably with confinements in patients who have not been operated upon, as I venture to think that most medical men would be well content if normal cases, in which even forceps were not required, formed 73 per cent. of their confinements.

We come now to the second part of this question of pregnancy. The first was, Does the operator affect the work of the obstetrician? The second is, Does the confinement undo the work of the operator? The 26 confinements were distributed among 21 patients; 3 of these were not seen afterwards; one was seen after the first, but not after the second, confinement, and in this case and in 16 others the uterus had remained well fixed up in good position. In the remaining case the uterus had a certain degree of mobility so that it could be partially retroverted, but it gave rise to no symptoms. We may, therefore, conclude that subsequent pregnancy does not interfere with the operative results.

(6) *The Abdominal Scar.*—Three patients had to be operated upon later on account of yielding scar; one of these was the stout, flabby person previously alluded to, and another had the wound weakened by suppurating stitches. Thirteen patients, including this last one, had stitch abscesses after operation. With better operative *technique*, and especially with the use of sterilised gloves during operation, the tendency to this trouble has greatly diminished in the later cases, only one case operated upon within the last 2 years having had a stitch abscess. These drawbacks are not inseparable from the operation, except in so far as patients with flabby abdominal muscles and fasciæ will probably show a tendency to yielding scar; and we may, therefore, confidently say that in the future we are not likely to have troubles arising from the scar in more than 2 or 3 per cent. of the cases.

If we sum up our sixfold test from the coldly statistical point of view, we find:—

(1) The general condition was improved or unaltered in 92½ per cent. of cases, the percentage of actual improvements being 85.

(2) The uterus remained firmly attached in 92 per cent., and had certain mobility in 5 per cent., giving 97 per cent. of successful results, with 3 per cent. failures.

(3) Not less than 95 per cent. of patients were permanently relieved of the need for pessaries.

(4) In 74 per cent. of cases the operation was followed by no bladder trouble; on the contrary, some were relieved.

(5) Of 40 pregnancies following operation, 4 had not terminated, 10 patients had miscarried, and 26 had borne living children. Of the 26 confinements, 19 had been quite normal, making 73 per cent. In only 1 case out of 21 was the uterus at all disturbed in its position, and then only partially, by pregnancy and confinement.

(6) The abdominal scar gave no trouble at all in 89 per cent. of cases; herniæ occurred in 2 per cent.

On statistical grounds it may be fairly claimed that the surgical treatment of displacements fulfils the requirements imposed in a sufficient proportion of cases (averaging 88 per cent. for all the tests) to justify its existence. But there is another aspect of the matter which is, if possible, more convincing, namely, the untabulated and unrecorded statements of patients as to their satisfaction at the doing away with pessaries and periodic examinations, their greater fitness for work and ability to get about, their loss of those bearing-down pains and that general discomfort and lack of energy which combine to reduce a woman to the condition of being "not ill, and yet never well." I must confess that I, at least, have been not a little influenced by these considerations; and I claim to be myself the most exacting critic of my results, because my interests and my satisfaction alike depend, not upon the making of many operations, but upon the securing of cured and grateful patients.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor R. de Bovis, M.D., Professor of Obstetrics at the Rheims Medical School. Subject: "How to Set to Work in Ordinary Obstetrical Practice."*

Session of the General Medical Council.

WE are officially informed that the Eighty-seventh Session of the General Medical Council will commence on Tuesday next, May 26th, at 2 o'clock p.m., under the presidency of Dr. Donald MacAlister.

ORIGINAL PAPERS.

SOME POINTS IN
SYMPTOMATIC ALOPECIA. (a)

BY DAVID WALSH, M.D.ED.,
Senior Physician, Western Skin Hospital, London, W.

THE subject of alopecia, or baldness, interesting as it is, from many points of view, has hardly yet had its proper share of attention. In various ways its study is of value to the medical practitioner, whose advice is constantly asked for on account of impending or of complete baldness. From the standpoint of scientific investigation a great deal remains to be learned with regard to the pathology and ætiology of baldness. Take as an illustration the ætiology of so common an affection as *alopecia areata*, which is simply in a chaotic condition—one set of authorities vigorously maintains its parasitic origin, another set is no less dogmatic in claiming it as a tropho-neurosis—while a third, with more reason, adopt the theory of multiple origin. The authenticated history of outbreaks of alopecia areata in schools renders it impossible to doubt the infection theory—on the other hand, it is clear that bald patches may follow a blow on the head, and that they are definitely connected with myxœdema. As will be shown later, there are phenomena concerned in one form of "band" alopecias which appear to be of an extremely complex origin and relationship to pathological processes in other parts of the body.

Alopecia may be partial or complete: it may be circumscribed (*areata*) or generalised: and it may be congenital or acquired.

A convenient classification is into congenital and acquired alopecia, the latter being subdivided into—

(1) Symptomatic.
(2) Senile.
(3) Premature or so-called idiopathic.
(4) Alopecia areata.

The congenital forms will not be discussed here. In dealing with the subject systematically it is convenient to divide the acquired alopecias into well-defined groups like the foregoing. As a matter of fact, they may all be ultimately allotted to the symptomatic group, whether their origin be due to invasion by fungus or bacterium, to nervous or to nutritional changes dependent on local or general conditions.

Space does not permit us to deal exhaustively with this interesting subject, but it is proposed to discuss a few of the many forms of symptomatic alopecia in the hope that some light may be thrown on the points of causation, diagnosis, prognosis and treatment.

A familiar diffuse thinning of hair in general practice is the acute toxic form met with after scarlet fever and other specific affections. As a rule, recovery is rapid and complete, provided the scalp has been previously free, or fairly free, from seborrhœa, and that the patient has a good constitution and attends to local cleanliness.

It sometimes happens, however, that complete recovery does not take place after acute maladies. Many cases of premature baldness in patients, say, from 20 to 40 years of age, may be traced to some such attack. For some reason or other measles is often the starting point of a chronic seborrhœa which ends in partial or complete baldness. The fall of hair during or after measles is probably due to damaged nutrition of the hair bulb by toxic products of the malady. According to the writer's view of the general law of the exanthematous rashes, there is an attempt of the skin, along with other excretory organs, to throw off the toxic factor or product from the body, with corresponding excretory irritation of all the parts concerned in the elimination. (b)

When the measles rash has subsided the hair should rapidly regain its normal condition of growth. When regrowth does not take place it is probably due to the development of seborrhœa, which may be regarded as a bacterial infection that is either a multiple invasion or due to a single micro-organism, the identity of which has not been yet completely established.

(a) Abstract of Lecture delivered at the Western Skin Hospital, May 14th, 1908.

(b) See MEDICAL PRESS AND CIRCULAR, October 22nd, 1890, and "Excretory Irritation." By David Walsh, M.D. London: Bailliere, Tindall and Cox. 1897.

The extent to which the hair falls after measles varies from simple thinning to complete baldness. As a rule regrowth takes place. It is interesting to compare with the above picture the facts of syphilitic alopecia. One of the earliest lessons of the student in the out-patient room is the almost invariable loss of hair that accompanies constitutional syphilis. In this case we can observe the whole process at our leisure. In the alopecia associated with early forms of eruption the hairs lose their natural glossiness, become dry, brittle, and come away freely in the brush. Not only the hair of the scalp, but that of the eyebrows, eyelashes, and all other hairy parts of the body, including the pubis, may be shed. As a rule, the hair falls uniformly from the scalp, but syphilitic alopecia areata is not uncommon. The patchy form is more usually associated with later syphilides of the papulo-pustular variety. In congenital syphilis there are various forms. In one case in a baby under the writer's care, there was a perfectly smooth area sharply confined to the frontal bones. Under anti-syphilitic remedies the bare part became covered with hair. In another form of hereditary syphilitic alopecia the scalp is covered with numerous roundish patches, the size of a sixpence or a shilling, over which the hair is partially denuded, giving the head a characteristically "moth-eaten" look. In adults the syphilitic alopecia may be inferred from its somewhat angular outline as against the rounded or oval patches of the ordinary form; it is often symmetrical, more or less covered with hair, and accompanied by frontal headache and other signs and symptoms of syphilis.

The course of syphilitic alopecia is curiously like that following an ordinary exanthem. As a rule, the hair grows again freely, but the hair may never regain its original luxuriance of growth; while, if complicated by seborrhœa, partial or complete baldness may result. It seems not unlikely, in the light of modern bacteriology, that the early alopecia of syphilis may be of toxic origin, while that of the later rashes is caused by the local presence of the *spirochæte pallida*. In either case, the undoubtedly beneficial action of mercury applied to the scalp may be explained on different grounds. Thus, in the early toxæmic condition it would be due to a general effect after absorption into the system, and in the germ-infected syphilide mainly to local germicide action.

A further consideration of these symptomatic alopecias from the point of view of treatment will furnish us with an illustration of the general principles that should guide the practitioner.

In an ordinary alopecia following, say, enteric fever, it is a familiar experience that a complete cure may be effected by natural processes. Satisfactory regrowth, however, may not follow on account of unfavourable conditions of the patient, which may be general or local. For instance, should convalescence be attended by anæmia, or chronic nephritis, or any debilitating condition of health, the hair may not grow again. If the general health cannot be restored by appropriate measures the chances of successful treatment of the alopecia are proportionately diminished. From this point of view it is just as necessary to give iron and cod-liver oil to a debilitated patient in order to encourage growth of hair as it is to apply local stimulant and antiseptic applications to his scalp. So far, we have no drug that we can say acts specifically as an internal stimulant to the growth of hair. We know that in some way the thyroid gland exerts a powerful influence upon the nutrition of hair. Its administration, however, in cases of baldness, is disappointing. As our knowledge of the physiological effects of the internal secretions is extended we may reasonably look forward to the discovery of a drug which, administered internally, will definitely promote the growth of hair. It is a familiar observation that in consumptives there is often a strong growth of hair, but a similar effect does not follow the use of tuberculin. Pilocarpin appears to be occasionally successful. Arsenic is credited by some authorities with the power of stimulating the growth of hair. If it be so the results are certainly capricious, and, in the author's opinion, do not warrant the internal administration of a drug that has been shown experimentally to damage all the channels of excretory outlet from the body. Who shall say what lasting harm is done to the kidneys, say, by a course of arsenic extended over one or two years, as often happens in hospital practice? After a prolonged trial the writer can state with confidence that he has obtained equally good results without arsenic, which he has ceased to prescribe except on the rarest occasions for many years past.

On the other hand, we have seen that certain toxic products of disease processes have the power of so disturbing the nutrition of the hair of the scalp as to cause it to be shed. There is a precise analogy to that in the case of thallium acetate, which has been found to cause alopecia when administered to check the sweating of phthisis. The alopecia has ceased with the discontinuance of the drug.

While it is desirable, and sometimes absolutely essential, to attend to any constitutional error in a patient suffering from alopecia, it must nevertheless be admitted that by far the more important part of treatment is, in the majority of cases, purely local.

External Treatment.—The first great principle of treatment is stimulation. This is readily applied by lotions containing such stimulant drugs as lysol, resorcin, salicylic acid, strong ammonia, or cantharides.

Systematic washing, it need hardly be said, is absolutely necessary under all circumstances. Any good antiseptic soap may be used for the purpose. Should there be much dandruff, it is well to use soft soap, or a shampoo of equal parts of soft soap and spirit for a few weeks; but this should not be continued indefinitely. The frequency of the washing should be regulated by the amount of dandruff, but, as a general rule, once a week should suffice. Where there is much seborrhœa, the main indication is to apply as far as possible the principles of antisepsis and asepsis to the scalp. This point was originally insisted upon by the present writer in 1902. (*a*)

Increasing experience has proved the value of antiseptic methods, so far as they can be applied, in dealing with all cases of alopecia at all ages. Without entering into detail, systematic cleanliness of brushes and combs is essential, together with aseptic hair-cutting.

Amongst other symptomatic alopecia, that which is connected with myxœdema is specially interesting. It is a well-known fact that when a monkey or rabbit is deprived of its thyroid, patches of alopecia areata develop in various parts of the body. In the human subject the hair changes in myxœdema are characteristic. One of the early signs is that the hair grows coarse and grey, especially along the anterior margin. It then becomes dry and brittle, and falls out, sometimes in patches, but more generally diffusely, until the whole scalp may be entirely bald. The process may extend to the eyebrows and rest of the hairy parts of the body. An interesting point is that under treatment by thyroid gland the growth of hair may usually be restored, and, what is more remarkable, the new hair may be as fine as the original texture, and of natural colour.

When these changes come on in the course of exophthalmic goître, it may be suspected that myxœdema has become superadded. In the writer's experience it is extremely common for exophthalmic goître to be followed, or even accompanied, by myxœdema. In these particular instances the condition of the hair is of positive diagnostic value, and there seems little doubt that as knowledge increases we may reasonably expect that the hair will become more and more a delicate index to the state of the general health.

The writer has noted the occurrence of a form of frontal band alopecia in connection with exophthalmic goître. It is congenital, and has been noted as a constant accompaniment of a fairly extensive series of cases of that malady. This congenital high forehead has been investigated in a large number of cases,

---

(*a*) "The Hair and its Diseases." By David Walsh, M.D. First Edition. London: Baillière, Tindall and Cox. 1902.

and in the majority is found to be connected with abnormality of the thyroid gland, tachycardia, nervousness, headache, and a group of vasomotor symptoms, such as epistaxis and chilblains or Raynaud's disease. This temperament the writer has called potential exophthalmic goître. In several instances the disease has developed in patients while under observation, after shock, or fright, or other depressing influence. The occurrence of a sharply-defined band of alopecia across the forehead is not capable of any ordinary anatomical explanation. Should this congenital sign be definitely connected with so obscure a symptom-complex as that of exophthalmic goître, the problem will be still more complicated.

So far as the hair changes in exophthalmic goître and myxœdema are concerned, the constant current, which has been recognised as an excellent treatment since Cardew introduced its use in 1891 for exophthalmic goître, has a potent effect also in restoring the normal growth of hair.

In cases of exophthalmic goître with or without myxœdema, the writer has seen excellent results from the application of a continuous current. The routine treatment of stimulant antiseptics to the scalp, of thyroid feeding and of electrical treatment, will often work wonders, not only in the restoration of the hair, but also as regards the tachycardia, nervousness, depression and the various vasomotor disturbances which accompany the condition.

In this combination of external and internal therapeutics we probably find the germ of the future scientific treatment of alopecia symptomatica due to more or less obscure constitutional changes.

For syphilitic diseases mercurial applications should be used—an ointment of red oxide or of the oleate, preferably. White precipitate is useful in connection with tar preparations and antiseptics such as salicylic acid.

One of the most valuable forms of stimulation is by means of the electrical current. Faradisation is useful, but far better results, as a rule, can be obtained by the constant current. A powerful battery and some skill are required in its use. The high frequency current sometimes produces brilliant results. In the near future there is a strong probability that more enlightened use will be made of electrical methods in the treatment of alopecia of all kinds. It is only by the development of a scheme of treatment based on scientific observation that one may hope to bring symptomatic alopecia under the control of the medical practitioner.

Finally, the treatment of alopecia, of all maladies, demands the most unwearied patience on the part of all concerned.

THE “EMPTY BRONCHUS” TREATMENT BY POSTURE IN THE BRONCHIECTASIS OF CHILDREN. (a)

By WILLIAM EWART, M.D.Cantab., F.R.C.P.,

Consulting Physician to St. George's Hospital, Senior Physician to the Belgrave Hospital for Children.

I do not propose on this occasion to go over the entire ground which was recently covered by my paper on “The Principles of Treatment of Bronchiectasis,” read before the East Sussex Medico-Chirurgical Society at Hastings, but rather to confine myself to the special points in the mechanical part of the treatment in children. This intractable disease, if it is to be cured at all, is more likely to be cured in childhood than at any other age. And the responsibility is great of not missing that better chance by delay.

A sad instance in point is the lamented death a few days ago of the little patient, W. C., æt. 5, who had suffered from the affection since an attack of pneumonia nearly three years ago. Her systematic treatment in July, 1907, by the inclined bed and by the prone posture on the All-Fours Exerciser was of very short duration owing to the temporary closure of the ward. When at last her mother brought her again a month ago, she had developed lardaceous disease and albuminuria. Although after a few days of postural treatment the expectoration was greatly reduced, so that even partial inversion did not lead to much being coughed up, the fœtor showed no improvement; and the probability that ulcerative and necrotic changes had occurred in the dilatations was borne out by the patient's rapid failure and final exhaustion; but an autopsy could not, unfortunately, be obtained. I believe that, had she been under continuous treatment during the last twelve months, she would have been, not only alive to-day, but probably vastly improved under the treatment which I have to describe to you as “The Empty Bronchus Method.” For there is reason to believe that a well-drained bronchus is also one that practically ceases to secrete.

The Principles of Treatment.—This brings me to say a word of introduction on the general question. There are two fundamental principles which must be carried out if any line of treatment which may be adopted is to be successful. One of them is to *empty the bronchus; and to keep it empty.* The other principle is to *fill the lung with air; and to keep it actively expanding.* These two objects were conveyed in the title of the paper published in the *Lancet* for July 13th, 1901, which marks the difference between the practice of this century and that of previous ones—“The Treatment of Bronchiectasis by Posture and by Respiratory Exercises.”

The Various Modes of Treatment.—On that basis various therapeutic measures may be founded with good hope of success. It is not my object to deal with them to-day, but it is right to enumerate them. (1) The latest, and that which is claimed by its author, Dr. Colin Campbell, of Southport, to be the most rational, and also the most successful in curing the affection, is the direct medicinal treatment of the bronchus by *intra-tracheal injections.* Unfortunately, it is not one easy of application in very young children. (2) Of great importance is also Arnold Chaplin's well-known method of *creosote inhalation.* It is applicable even in young children, and it is recognised to be the most effectual means of overcoming by medicinal agencies the fœtor of the expectoration and of the breath. (3) In the third place, we have a variety of internal remedies which I need not enumerate. And, lastly, (4) a large assortment of inhalations made available by methods to which I may presently refer.

The mechanical methods which I have to urge as essential adjuncts to these various plans combine two objects, *the bronchial and the pulmonary,* which are distinct, but possess one great feature in common—they are both intended for *continuous application,* in the strict sense.

The Intermittent Postural Treatment.

The bronchial treatment is mainly postural. It is strange that the obviousness of this indication should have so long escaped notice. My own earliest employment of the *ultra-prone position, or inversion,* dates back many years in connection with the emptying of basic cavities in phthisis. It was not a novel device, at any rate in this country, and had been advocated and practised before. It is the type of what I shall term the *intermittent postural method,* which should rightly be connected with the name of H. Quincke (a), of Kiel. In 1898 he published his short but weighty “Contribution to the Treatment of Bronchitis,” in which he suggested the inclined prone position for adoption for comparatively short periods once or twice daily, for the sake of bronchial drainage in cases where this was wanted. In October, 1900, Jacobson (b) published a further account of the method, with cases in which the inclined posture had been used for periods of one hour once or twice in the course of 24 hours with favourable results. These papers were not known to me until I consulted the literature in connection with the publication of my own paper mentioned above. In the latter I advocated the *continuous postural*

(a) **Read before the Society for the Study of Disease in Children, May 8th, 1908.**

(a) *Berlin Klin. Woch.*, 1898, p. 525.
(b) *Ibid*, 1900, p. 904.

method by keeping the patient in bed, and by raising the foot of the bed considerably so as to keep up a strong downward slant from the bronchi to the larynx, whatever the positions might be into which the patient might turn during sleep.

The intermittent "ultra-prone" posture or "inversion" is the most rapid and effectual for the evacuation of accumulations in the cavities of phthisis or of bronchiectasis. The patient leans over the side of the bed or of a table, placing the hands on the ground, so that the long axis of the thorax approaches to the vertical. A few coughs will rapidly clear away the greater part of the collection. The method is fortunately available in children in a degree not to be attained in the adult, for even up to adolescence they are not alarmed at the thought of "standing on their head." Infants will bear to be held vertically head downwards, and in small children something approaching to actual inversion may be safely resorted to. These extreme positions, in which patients are encouraged to cough and to expectorate, are exceedingly useful for dislodging remote accumulations, and it may be possible to improve the opportunity by the judicious application of bi-manual pressure at the base of the thorax judiciously performed and limited to the period of expiration. As a fact, *absolute* inversion is not necessary. The child may be either held in the ultra-prone position by the nurse, or laid across a low chair or a stool, head and hands downwards, in imitation of the procedure in the adult.

The intermittent prone postural method of Quincke is likely to come into extensive use in various affections, and I have devised with that view, and had constructed, a set of appliances or machines enabling me to apply the prone method with graduated inclinations and lateral positions, according to the requirements of the case and of the affection under treatment.

THE CONTINUOUS POSTURAL TREATMENT.

The Continuous Treatment has three practical instalments: *The Nocturnal postural treatment; the Diurnal postural treatment;* and the *Respiratory treatment by means of the Elastic Belt and of the "Exerciser."*

(1) *The Costo-Abdominal Elastic Belt* should be worn during the night as well as the day, for its virtue is active for good during each breath that is drawn. If this were neglected, the loss of advantage to a child during the 10 hours' night sleep might be easily reckoned up in figures to an important total. The belt itself, made of waterproof material, easily washed and dried, has its buckles in front, and at one or both sides an insertion of a lacing of indiarubber cord or tubing. It is mainly *abdominal*, extending some way below the umbilicus, and upwards not quite as far as the costal arch. But I have found it useful to attach to it in the back a *lower thoracic elastic band*, one or two inches wide, also buckled in front, which, being quite separate except over the spine where it is continuous with the belt, can be carried obliquely over the costal arch, and its buckle fastened to the night-gown by a safety pin at any level desired. Its pressure can thus be regulated nicely so as to be just sufficient to stimulate the costo-abdominal breathing. I have explained elsewhere the probable mechanism of the advantage accruing to the upper costal breathing from wearing the abdominal belt. The recurring stimulation of the diaphragm with each expiration by the artificial elastic recoil of the abdominal contents calls reflexly into action some of the apparatus for extraordinary respiration, and in particular the upper costal muscles, whilst it directly amplifies in a marked degree the inspiratory excursions of the diaphragm. It goes without saying that judgment is requisite in dealing with so active a therapeutic agent.

(2) *The Nocturnal Treatment.*—This should be made as effectual as possible. Everything depends upon the declivity of the inclined plane being effective, not, as might happen, illusory. In the first place, as the distance from the diaphragm to the larynx is so short in a little child, *the angle* of the inclined plane must be relatively greater. In the "Bronchiectasis Cot," which I have to describe, the foot end of the "fracture-bottom" bottom must therefore be secured to its graduated support at a higher level.

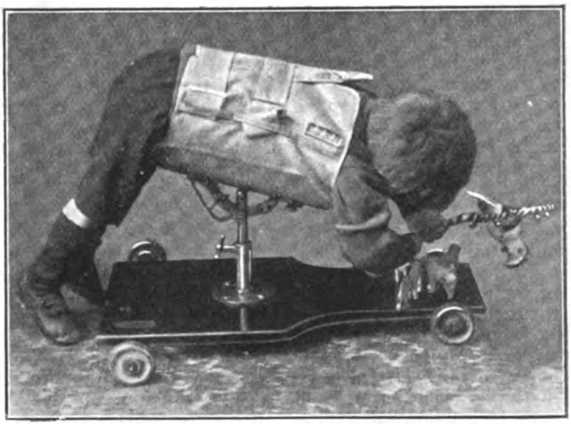
The "Bronchiectasis Cot" is easily prepared in the case of the ordinary bed-shaped cot with high end rails, as well as side rails. A fracture-bottom is placed under the mattress, and its foot end must be raised to the desired height by means of the *graduated support;* the other end extending as far as the head rail.

The graduated support is simply a firm board of sufficient width, from which project two thick movable wooden pins to bear the weight of the foot end of the fracture-bottom. The board is perforated with two parallel vertical rows of holes to receive the pins. A strap passed through two of the holes not in use and round the upright rails will ensure its stability. This or some similar contrivance will be found convenient for hospitals, as it occupies little space for storage and offers the choice of several positions to suit various cases. For private patients it is easy to obtain the same result by slinging the end of the fracture-bottom on a rope fastened to the foot posts, and passing underneath through eyes or holes to prevent any slipping.

The mattress having thus been duly slanted, it is necessary, in the second place, that the slant of the thorax itself be made a genuine one by posture. It is clear that, let the degree of inclination be what it may, if the child were to lie transversely to the cot the long axis of the chest would be horizontal, in spite of the inclination; and as this almost invariably happens it will be often found necessary to let the child lie between two sandbags, which will also afford assistance against the tendency to slide down the slant "into a heap." In the groove thus formed the child can lie in any decubitus; the more this is varied so much the better.

Another practical point is *the bolster.* The bolster must be *small and firm*, for the support of *the head only;* and to this effect it should be secured to the head rails so as not to be displaced. The ordinary square pillow and squash bolster are quite unsuitable, as they extend under the shoulders and thus modify the inclination in the direction of the horizontal. With these practical precautions the nocturnal instalment of treatment becomes one of the most important.

(3) *The Diurnal treatment* is, as previously stated, the agent *par excellence* of pulmonary regeneration, whilst it also affords the most effectual means, next to inversion, for drainage. The prone posture which is to be kept up, is anatomically the most direct for that purpose (the greater bulk of the lung being posterior) and brings to bear the active force of the respiratory pump for emptying the sacculations by lateral compression. The All-Fours' Exerciser, upon which the prone treatment is conducted, is a small edition of one of the arrangements which are provided for in my "Convalescent Machine" for the adult. The supporting body trough, upon which the child is secured by a broad belt is provided with three sets of movements regulating its height and its inclinations from end-to-end and from side-to-side. The lateral inclination is usually not called into play here. It is



specially used for the lateralisation of the chest in empyema, pleurisy, and other conditions requiring special unilateral measures of rest or of re-expansion.

The end-to-end declivity required is that which will bring the shoulders appreciably lower than the hips, and at that angle the child is made to recline in the prone position.

Prone Exercising.—The height of the body trough is to be so adjusted as to allow free use of the four limbs—the feet for propelling the machine (the front wheels of which might be made also workable by the hands), the arms and hands for any appropriate work or amusement. In this way, quite independently of any of the dumb-bell and *respiratory exercises* for practice at stated intervals, a good deal of activity is thrown upon the limbs and the neck, and this brings fully into requisition the posterior and basic pulmonary districts. A table can be improvised in front of convenient height for drawing or writing, and to hold the book for reading, or cushions to rest the head. *Prone Exercising* need not, therefore, imply idleness or complete interruption of the lessons.

"*The All-Fours Exerciser*" for Children (*a*), and the "*Convalescent Machine*" for Adults (*b*), illustrations of which are included in my paper, "On Convalescence and Its Stages" (*c*), are purposely adapted for most varied medical and surgical affections. They are therefore specially suitable for hospitals and institutions, where they can be in constant use, thanks to their adjustability. But for a makeshift, and as only one position is required, any individual case of bronchiectasis in a child is easily extemporised by padding a high stool, cutting down its legs to the extent desired, and finally mounting it upon wheels. Or we may adapt for our purpose, with slight modifications, Dr. Tucker Wise's "Inclined Plane for Phthisis," a description of which he has kindly communicated to me in advance of its impending publication in the *Lancet.*

The Rationale of the "Empty Bronchus Method" has probably been made clear by the foregoing practical description. It aims at stopping the bronchial irritation and hyper-secretion by bronchial drainage and by pulmonary ventilation, and at reclaiming for active pulmonary expansion the thoracic space usurped by the dilatations and by the fibrous tissue. This vicarious pulmonary development is eminently attainable in childhood, and therefore within our own gift; let it not be withheld. As even one day of this treatment is a gain, every succeeding day will be a further step towards a cure.

Is any further treatment necessary? Advanced and neglected cases may need a good deal more of it than could be discussed here. Early cases will certainly need very little. But for both sets of cases *inhalation* is of value. The simplest form is the *Respiratory Bib,* a twofold piece of flannel soaked in terebene or other inhalant, and enclosed in an open bag of jaconnette to be secured between the night-shirt and under-vest, just below the collar, so that the impregnated air is constantly being inhaled.

The dry Bottle Inhaler, filled with horsehair and with small pieces of blotting-paper steeped in the inhalant, is a variation on the same theme, acceptable to children for variety's sake, and because of the tube and its mouthpiece. Whether they blow or whether they suck through it, none of the strong fluid can come into their mouths.

These devices will generally render unnecessary the more searching treatment by the creosote chamber, even in cases of fœtor. But, in conclusion, they also may be superfluous if the rational treatment be conducted, instead of in a crowded town, in the pure air of the mountain or in the strong air of the sea. *Atmosphere and climate* are the most potent and sometimes the most indispensable of our adjuncts, and in children they are likely to produce results not to be equalled in the treatment of adults.

(*a*) Constructed for me by Mr. G. P. Turner, of 16 Eccleston Street, S.W.

ON THE DIAGNOSIS OF HÆMATURIA.

By ANDREW FULLERTON, M.D., F.R.C.S.I.,

Hon. Assistant Surgeon to the Royal Victoria Hospital and the Belfast Hospital for Sick Children.

The diagnosis of the cause and source in a case of hæmaturia is not always easy, especially when the apparatus for directly illuminating the parts is not available. Certain definite rules have been laid down by writers on this subject for the guidance of the practitioner, but it must be freely admitted that, if these alone are relied upon, frequent mistakes will be made. Indeed, the cystoscope, and, I might add, the urethroscope must be used for the purpose of correcting or verifying the diagnosis.

With regard to the *colour* of the urine, we are taught that when the fluid is bright and arterial looking, the source of bleeding is near the outlet—bladder, prostate, or urethra. While this rule is of value, too much dependence must not be placed upon it, as a good deal depends on the quantity of blood present and the length of time it has lain in the bladder. Quite frequently we see bright red blood in the urine when severe hæmorrhage has taken place from the kidney. In cases of kidney tumour, for instance, the hæmorrhage may be very free, and be passed *per urethram* almost as it comes from the kidney. This occurred in a case of congenital cystic kidney which I saw last year with one of my colleagues. The patient lost enormous quantities of blood, and was reduced to a condition of the most extreme anæmia. I found on cystoscopic examination that the blood issued from the right ureteral orifice. The diagnosis was confirmed by subsequent inspection of the kidney, which was removed. Unfortunately, the other kidney, which was also cystic, did not prove adequate to the demands made upon it, and the patient died from uræmia.

I have also seen bright arterial blood passed in a case of injury to the kidney by a buffer accident. Cystoscopic examination in these cases is most difficult if the ordinary instrument is used. It is much better to use a washing-out cystoscope like that described by Dr. Newman, of Glasgow. In this instrument the telescopic portion of the apparatus can be removed, and the bladder washed out, without removing the cystoscope, from the urethra. A similar instrument is the newest form of Casper's catheterising cystoscope, sold by Schall, of London. This instrument is the most efficient and convenient I have yet seen.

When the colour of the urine is dark, and the blood intimately mixed with it, we are taught that the blood probably comes from the kidneys. This rule is also useful, but frequently leads the practitioner into grave error. I was asked the other day to cystoscope a patient who was passing without pain dark, port-coloured urine, with a view to ascertain which *kidney* was affected. The patient was a man, aged about 60. I found the ureteral efflux normal from both sides, but at the base of the bladder there was a large carcinomatous ulcer with numerous dark points from which hæmorrhage was taking place sufficiently slowly to allow the blood to mix intimately with and be acted upon by the urine. So much for the colour of the urine.

Now, with regard to the *time* at which the blood appears in the stream. If it appears at the end of micturition, the source of the hæmorrhage is probably prostate or bladder. The bleeding is caused by the contraction of the bladder producing engorgement of the vessels of the mucous membrane, with the result that if inflammation or ulceration is present, the thin-walled vessels rupture, and blood is forced out with the last drops of urine. This is quite frequently seen in cases of stone, in cystitis, and in Bilharzia hæmatobia. It is also sometimes seen in cases of enlarged prostate.

If the blood comes just before the stream, it must have lain in the prostatic urethra or at the neck of the bladder, shut in temporarily by the compressor urethræ muscle. In cases of enlarged prostate one occasionally finds this sequence of events.

Lastly, if the hæmorrhage occurs quite independently of micturition, dripping or flowing from the meatus, it must be due to trouble in the urethra. I need not here do more than refer to the cases of urethral hæmorrhage due to rupture, instrumentation, etc., so common in hospital practice. I have recently seen a case of very severe hæmorrhage due to papillomata of the urethra. In this case the diagnosis could only have been made by actual inspection of the canal. After removal of the growths the bleeding entirely ceased.

The *size and shape of the clots* will help one to form some idea of the source of the hæmorrhage. Large clots are much more frequent in cases of hæmorrhage from the bladder. Here again, however, much depends on the quantity of blood poured out. Large clots may form in the bladder in cases of severe hæmorrhage from the kidney. Small, worm-shaped clots moulded in the ureter will often suggest the origin of the hæmorrhage. These must not, of course be confounded with the larger clots formed in the urethra and forced out at the beginning of micturition.

Cases of hæmaturia may be divided into two great classes: those associated with pain, and those in which this symptom is entirely absent. I propose briefly to discuss the vesical group of the latter class of cases.

In addition to the renal group of painless hæmaturias, discussed in a recent article, (*a*) we have the vesical cases, due, as a rule, to tumours, innocent and malignant. A typical case is the following: A man, æt. 30, was sent by his medical adviser with the history that for the past two months he had been passing blood in his urine. He had no frequency, but complained sometimes of pain across his loins. The blood-stained urine was arterial in colour, and, according to the patient's statement, blood sometimes preceded micturition, and sometimes occurred at the end of the act. The introduction of the cystoscope caused considerable hæmorrhage, which was with difficulty controlled by adrenalin. On obtaining a clear medium a large villous tumour was seen to the left of the internal meatus. This was removed by supra-pubic cystotomy, and is an excellent example of this form of growth. The tumour was single and sessile. A portion of the mucous membrane at its point of attachment was excised with the tumour to prevent recurrence. The edges of the cut mucous membrane were brought together by fine catgut sutures. I have already mentioned an example of malignant tumour of the bladder where the blood, instead of being as one might expect, bright red in colour, was dark and intimately mixed with the urine. No operation was undertaken in this case. I might also refer to a case of carcinoma which occurred in an old man, æt. 80, who lost large quantities of blood. He was thought at first to have enlarged prostate, but on cystoscopic examination a rounded projecting tumour was found, ulcerated on its free surface, growing from the anterior wall of the bladder. A supra-pubic cystotomy was subsequently performed by another surgeon for the relief of retention. The growth was then found to have invaded the internal meatus. Bilharzia hæmatobia may give rise to a painless form of hæmaturia, as seen in the following case. A man, æt. 26, was sent to me on account of the presence of a small quantity of blood in the last few drops of urine. He had been a soldier in South Africa during the recent war, and had contracted the disease there. He passed blood also in his motions. The characteristic ova were found in his urine, and on cystoscopic examination collections of ova, white in colour, and resembling miliary tubercles, with patches of hæmorrhage and ulceration, were found on the posterior wall of his bladder.

Lastly, one occasionally sees cases of painless hæmorrhage due to rupture of varices of the bladder. After washing out with adrenalin, a small clot may be found in the vessel at the seat of rupture.

It will be seen from the cases I have described, that without great care and the intelligent use of the cystoscope and urethroscope it will be impossible for anyone to diagnose accurately the many causes of hæmaturia, especially those very puzzling cases of painless hæmaturia which, in my experience at any rate, are tolerably frequent.

SOME CONSIDERATIONS REGARDING

PNEUMONIA IN CHILDREN,

DRAWN FROM AN ANALYSIS OF 500 CASES. (*a*)

By G. H. MELVILLE DUNLOP, M.D.Ed., F.R.C.P.,

Lecturer on Diseases of Children in the University of Edinburgh; Physician to the Royal Hospital for Sick Children, Edinburgh.

The author remarked on the difficulties which beset any attempt at classifying a series of cases of this disease. Clinically, it was sometimes impossible to say whether a pneumonia should be looked on as a lobar or a broncho-pneumonia, while pathologically broncho-pneumonia was often found to have a lobar distribution. He had adopted the ordinary grouping into lobar, and broncho-pneumonia, (*a*) primary, (*b*) secondary, and when the record of the case left the precise nature of the malady in doubt it had been reckoned among the broncho-pneumonias. It was well known that irregular types were met with which it was difficult, or even impossible, to allocate definitely. Of the 500 cases, 147 were lobar-pneumonia, 85 being boys and 62 girls, a ratio of about 3.2, which was in agreement with the statistics of other observers. Analysing the cases with reference to age, it appeared that 12 had occurred under one year and 45 during the first two years. The majority of the patients were admitted during the winter and spring months. In 88 of the 147 cases the base of the lungs was affected. The order of frequency in which involvement of the lobes occurred was—left base in nearly half of all cases, then right base, and least frequently the left apex. The cases of lobar-pneumonia fell into three groups according to the time of onset of the physical signs. In 7 cases, which nevertheless were apparently genuine instances of pneumonia, no physical signs were detected. In another series the signs were delayed until the crisis approached, and in a third, largest group, the signs developed early in the usual way. Among the earliest signs of pneumonia he laid stress on a tympanitic percussion note with muffled breathing. Crepitant râles,

---

(*a*) Read before the Edinburgh Medico-Chirurgical Society, May 6th, 1908.

which were so characteristic of the disease in the adult, was usually absent in children. Of the initial symptoms, vomiting, which was present in two-thirds of the cases, was the most common. Convulsions were rare. Rigors were not very frequent; diarrhœa occurred in a good many cases. In several instances an acute onset with vomiting, fever, and abdominal pain had led to the patient being admitted to hospital with the erroneous diagnosis of appendicitis. The most common cerebral symptom was delirium, which occurred in 25 cases, the majority of them being children over five years. Herpes was present in 119 cases; it does not appear to occur in infants. The temperature seldom rose much over 105°; temperatures above this were ominous. One case of temperature of 107.5° occurred in the series. Crisis usually took place on the eighth day, but might be postponed until the twelfth or even twentieth day. For cases in which the disease terminated early, after 24 to 48 hours, he thought it was a pity that the term acute congestion of the lungs had to such a large extent fallen into disuse. It seemed to describe these very accurately. Empyæma was the most common complication, and sometimes, although it was strongly suspected, pus could not be detected by the needle. He instanced one such in which despite repeated failure to withdraw pus, a rib had been resected. A large piece of leathery fibrin was extracted, followed by a gush of pus. The temperature fell by lysis in 29 cases. Post-critical rise of temperature was common. Slowing of the pulse, at times down to 50 or even 40, and irregularity of the heart's action were met with in a number of patients, but there had been no instance of sudden collapse after the fever subsided. The mortality was 10 per cent.; the disease was most fatal during the first two years. The cases of broncho-pneumonia numbered 353, of which 120 were primary, and 233 secondary, to such diseases as measles, whooping-cough, bronchitis, rickets, diarrhœa, etc. The symptoms of primary broncho-pneumonia differed from those of the lobar form, in that the cough and dyspnœa were greater, and the temperature was more remittent. There was generally a morning fall of one or two degrees, though some times the type of temperature was reversed and the morning temperature higher than that of the evening. Fits occurred in 30 of the cases. The duration was from 2 to 35 days—longer, on the whole than in secondary broncho-pneumonia. Of the 233 cases of secondary broncho-pneumonia, 92 occurred in children over two years. It was impossible, clinically, to distinguish capillary bronchitis from broncho-pneumonia, and the diagnosis must often rest on the rising temperature, increased respiration, and cyanosis. Owing to the small size of the patches in many cases no physical signs of consolidation could be detected. Not infrequently the temperature rose rapidly shortly before death, and sudden death from heart failure, or from convulsions was common. The mortality was higher than in croupous pneumonia, being 25 per cent. Factors which unfavourably influenced the prognosis were pre-existing diseases, such as rickets and diarrhœa, and malnutrition. Among the points which aided in the diagnosis between broncho- and croupous-pneumonia were the distribution of the patches of consolidation, the temperature curve, and the fact that cough and cyanosis were more prominent symptoms in the former than in the latter. Statistics from various sources gave differing rates of mortality; this was to some extent attributable to the ages of the patients. In hospitals from which infants were excluded the mortality was naturally much lower than in foundling hospitals. The figures he gave—10 per cent. for croupous and 25 per cent. for broncho-pneumonic, were based on cases occurring at all ages up to 12 years. With regard to treatment the following measures were referred to as those on which he relied. In croupous-pneumonia nursing was the principal thing, and drugs were not always required. In all cases the food should be light, and care should be taken not to distend the abdomen and so further embarrass the respiration. Plenty of ventilation was essential, but he had not ventured to try open-air treatment in acute pneumonia. He often employed light poultices consisting of one part of mustard to four parts of linseed, applied for a few moments at a time every few hours. Instead of steam, he hung round the cot, on a screen placed at its head, towels soaked in hot water and sprinkled with eucalyptus. For reducing the temperature cold sponging was best. Cough mixtures he seldom employed. If the heart failed he gave strophanthus and strychnine; inhalations of oxygen were serviceable in cases of cyanosis. In secondary broncho-pneumonia alcohol was given as a routine.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Radical Cure of Inguinal Hernia in Adults.—Mr. Willmott Evans operated on a man, æt. 47, who had suffered from inguinal hernia for fifteen years. It was difficult to keep back the hernia with a truss, and as in his work as a railway porter the patient had to do heavy lifting he was advised to have a radical cure done. The hernia was reducible, and at the operation the contents were returned into the abdomen. The patient was anæsthetised and an incision three inches in length was made parallel to and three-quarters of an inch above the inguinal ligament; the inner end of the incision was placed a little external to the pubic spine. A few touches with the knife deepened the incision until the sac was reached; this was then completely separated from all surrounding structures and the inguinal canal was examined. It was found that the canal was decidedly shortened, the internal ring being almost opposite the external ring. It was decided to remake the inguinal canal. By means of scissors the aponeurosis of the external oblique was slit up from the external ring for a distance of two inches. The hernial sac was ligatured opposite the internal ring after it had been opened to see it contained nothing, removed on the distal side of the ligature and the stump was returned to the abdomen. Sutures of silk were then inserted so as to draw together the lower border of the arching fibres of the internal oblique and transversalis; these stitches were of the mattress form, and care was taken that they were not tied too tight; thus a new posterior wall of the canal was formed. The spermatic cord was replaced so as to rest on the new posterior wall, and the severed edges of the aponeurosis of the external oblique were also drawn together by mattress sutures, an external ring only sufficient for the cord being left. Two small superficial vessels required ligature, and the superficial wound was united by Michel's suture clips. Mr. Evans said that in considering the advisability of operation for the radical cure of inguinal hernia in adults the surgeon has to bear in mind several points: in the first place he has to consider the age of the patient; it is rarely advisable to do a radical cure on a patient over 55 or 60 years of age, though, if his general health is good and he is young for his years, if especially his arteries are not hardened, it may be done. On the other hand, even if a patient is below fifty, an operation for radical cure may not be advisable if the general health is bad or marked disease of any important organ is present. The occupation also of the patient is a factor in the matter; if it is arduous, requiring great physical exertion, a truss is not, on the whole, so satisfactory a method of treatment as is a radical cure. Further, if the patient is to remain in England a truss will be more satisfactory than if he has to go to some uncivilised country where a broken truss probably could not be repaired and where a strangulated hernia could not be treated. The question then arises, if it has been decided to operate, what operation should be performed: the answer depends entirely on the degree of hernia present; if the case is slight and the inguinal canal is not at all diminished in length then, in his opinion, all that is necessary is to ligature the hernial sac opposite the internal ring and cut it away on the distal side of the ligature. If this removal of the sac is thorough, the ligature being applied sufficiently high, no return of the hernia need be feared; in fact, the operation done is exactly that which he always performs for inguinal hernia in children. If, however, the hernia is of a more marked degree, the inguinal canal will have become shortened, the internal ring approaching the external. In these cases the canal has lost its protective power, for the natural mode in which a hernia is prevented in a healthy person does not depend on the smallness of the inguinal ring, but on the obliquity of the inguinal canal, owing to which increased abdominal pressure presses the posterior against the anterior wall of the canal, so that the greater the abdominal pressure, the greater the difficulty of the production of a hernia. In those cases of hernia in which the inguinal canal has become materially shortened, mere ligature and removal of the hernial sac will not suffice to prevent a return of the hernia; it is necessary to remake the posterior wall of the canal so that the canal is lengthened. With regard to the deep sutures employed, he sees no objection to silk; silk sutures will never cause suppuration, leading to extrusion, if care be taken with regard to asepsis, and also with regard to avoidance of excessive tightness when the suture is tied; a tight suture leads to strangulation and necrosis of the tissue included within the suture, this need not occur if the excessive tightness is avoided. The mattress form of suture was certainly the best for uniting aponeurotic structures, for by it flat surfaces are brought into contact, and not mere edges. With regard to the dangers of the operation, if perfect asepsis be employed there is only one danger of any importance, and that is injury to the bladder; the bladder is no rare constituent of an inguinal hernia; it does not lie within the serous sac, but is generally attached to the outside of the sac wall, and if the surgeon is not alive to the importance to the occurrence of such a complication the bladder may be wounded during the dissection, or may even be included within the ligature if the sac has not been thoroughly cleared from surrounding structures. The surgeon must always bear in mind the possibility of the presence of the bladder, and should any doubt arise in his mind whether or not some structure present is the bladder, the introduction of a metal catheter *per urethram* will speedily settle the point. Michel's sutures form a very convenient and simple method of uniting skin wounds. They can only be employed where there is no tension. The only harmful result that follows their use is a little local inflammation which may occur if too much pressure is employed in introducing them.

The wound healed by first intention, the Michel's clips were removed on the eighth day, and the patient left the hospital eighteen days after the operation. When allowed to sit up he was fitted with a Day's truss, not from any suspicion of the thoroughness of the operation, but because Mr. Evans considered that the support afforded by a suitable truss was useful until the abdominal wall recovered fully from the effects of the operation. The truss was to be left off some four months after leaving the hospital.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, APRIL 24TH, 1908.

The President, A. F. DIXON, M.B., in the Chair.

COLOUR FATIGUE.

PROFESSOR T. H. MILROY, in making a communication on the above subject, said that experiments had been frequently carried out in order to study the effects produced by partial or complete fatigue to various colours. Such effects as we term negative coloured after-images may be regarded as partial fatigue effects, whether the view of Young-Helmholtz or that of Hering be regarded as correct. According to the former theory, the after-image effect is due to the white light stimulating the nerve endings not fatigued by the original light—that is to say, it is a partial fatigue phenomenon. According to the latter theory, the after-image effects are due to an opposite change occurring in the visual substance to that produced by the original stimulus. In order to obtain more complete colour fatigue, different methods have been employed. Burch produced fatigue by condensing sunlight upon the eye, passing the light through transparent coloured screens, and studied the after-effects on colour vision. In this way he was able to produce conditions somewhat similar to those existing in the colour-blind. The method of excitation in this case is of such a severe character that some doubt has been expressed as to the validity of the results. Nagel, of Berlin, produced fatigue for red by wearing spectacles with orange-coloured gelatine films. Fatigue of a definite character was produced after wearing the glasses for one or two hours. This observer found that after this time he was red colour-blind for one or two minutes, having all the sensations of the dichromatic. I have employed this method for producing fatigue, and also another one depending upon the excitation by discontinuous retinal stimulation with spectral light. This flicker method, if the spectral light be intense, is very satisfactory in so far as fatigue phenomena are soon apparent. Discontinuity in stimulation may be easily brought about by rotating in front of the collimator slit of the spectroscope a disc with variable open sectors. On fixing with the eye the red part of the spectrum, fatigue is produced for that colour, and usually, if accurate fixation be adopted, within a very short time The study of the fatigue phenomena, however the condition may have been produced, is difficult, unless the fatigue be very pronounced, because the condition so rapidly disappears and the visual sensations alter with bewildering rapidity. One may study the fatigue phenomena by comparing the spectrum before and after the stimulation, or by testing with Holmgren's wools or similar tests, or by examination of successive or simultaneous contrast phenomena. After prolonged fatigue for green, the changes in the spectrum are seen in the green, yellow and orange mainly, the yellow encroaching on the red of the spectrum, while on the other side there is a gradually increasing admixture of white until the green tint disappears. In matching colours there is always a difficulty, even in slight fatigue for green, to distinguish between pure greens and bluish greens. Some of the most interesting fatigue phenomena are to be seen in testing successive and simultaneous contrast in the fatigued eye. For a fairly long period after fatigue for green there are changes in the simultaneous induction phenomena which are met with in the normal person when he observes a grey disc on a red field, either as carried out with Meyer's papers, or with a rotating red disc having a narrow circular grey band midway between the centre and the periphery of the coloured field. Under normal conditions the grey field appears of a green colour. This does not occur in the case of the person fatigued for green. In fact, the grey field shows no green tint until long after the slight red-coloured after-image has disappeared. It is advisable not to examine for these induction effects until time is given to allow the slight negative after-image effects to disappear. The advantage of these contrast effects as tests for colour fatigue and colour-blindness lies in the fact that they arise under conditions which, if we believe Hering's theory, necessitate a definite change in a visual substance due not to a stimulus from without solely, but also to an autonomous change. These colour sensations due to autonomous changes may be of special value as tests in cases of colour fatigue and blindness, for the reason that there is not the same opportunity for recognition of qualities in the stimulating body, other than the colour quality, as may occur in retinal stimulation resulting from coloured light from a definite object in the visual field. A colour-blind person may be able to match certain coloured wools by certain differences in the intensity of the saturation, illumination, texture, etc., although the colour sense necessary to the normal person in making the matches be actually absent, or at least deficient, in the case of the former.

Professor THOMPSON said that the explanation which he had always in his mind in the case of a grey patch on a coloured ground was that the judgment in the case of a given colour depended in a large measure on the prevailing colour of the field. Thus, in the example before them of a grey patch in a green field, one judged that the green field overspread the whole area, and so one subtracted green from the central white disc, which appeared, therefore, of a pink tint. He thought that these contrast effects, referred to in connection with fatigue phenomena, supported to some extent the theory of Hering, in which he had not hitherto believed very strongly.

Sir HENRY SWANZY said the communication and demonstration were exceedingly interesting, and dealt with a subject concerning the physiology of vision which was of extreme difficulty.

Professor MILROY replied.

A METHOD FOR THE EXAMINATION OF THE FISSURE OF ROLANDO.

Dr. C. R. CRYMBLE said that Professor Symington and he had examined the central fissure of the brain, and had studied specially its surface form, its walls, and its floor. Their first difficulty was to obtain records of a number of central fissures. They found that, as the fissure crossed the convex surface of the hemisphere, a photograph only gave a true picture of about one-third of the fissure. However, they were able to examine about forty brains by means of tracings taken on a sheet of xylonite moulded to the brain. After this a block of brain substance containing the central fissure was cut out, the fissure opened, and its floor cut through, so as to separate the anterior and posterior walls. Photographs of the walls, and of the different varieties of central fissure and floor were exhibited, the anterior wall showing convexities and the posterior showing concavities. It had been stated that as a rule the floor was shallowed by a deep annectant gyrus in the region of the superior genu, and this had been taken as showing that the central fissure had developed in two parts, but they had found only one specimen in twenty-four brains showing that condition, and it was only slightly marked. Slides were shown summarising the work of the observers. Authorities agreed that the superior genu was produced by a buttress on the anterior wall. There was a difficulty about the inferior genu. It was stated to be a curve of the fissure about the junction of the middle and lower thirds, opposite a transverse branch of the post-central fissure, but they frequently found two such branches. They had taken as a guide to it a buttress on the posterior wall fitting into two well-marked buttresses on the anterior wall. They found some difficulty in coming to a definite conclusion about the buttresses on the anterior wall, but were inclined to recognise two main buttresses, both exhibiting a tendency to sub-divide. They only found one specimen showing two single buttresses on the anterior wall, while ten out of twenty-four showed two main buttresses which partially sub-divided, making four buttresses; many showed one sub-divided and one single. The upper buttress produced the superior genu, and in it was said to be located the trunk centre. They believed that the concavities on the posterior wall were produced by the buttresses on the anterior wall.

Professor SYMINGTON said he thought the results obtained by Dr. Crymble and himself showed that, although a large amount of attention had been devoted to the anatomy of the central fissure, the methods pursued had been by no means satisfactory. Physiologists had, as a rule, depended on diagrams for their illustrations of the areas they stimulated, and it seemed to him that our knowledge of the exact position of a number of the motor centres had not been so accurate as they might have been if they had had some method of taking tracings of the fissure with an indication of the exact points where the stimulation was applied. Some surgeons attached great importance to the inferior genu, and yet they had great difficulty in determining from the text-books its exact position.

Dr. MOORHEAD stated that some years ago he had been asked by Professor Cunningham to investigate the fissure of Rolando, and it was possible that from a study of these specimens he came to the conclusion that there was a bridge in the fissure. He had had a brain from a person whose arm was greatly diminished in size, and no change had been noticed in the brain as regards the size of the arm area, but there was a distinct gap behind the arm area in the fissure of Rolando.

Professor THOMPSON said he regarded the bulgings seen on the anterior face as the strongest confirmation, apart from the actual physiological evidence that had been produced, that the grey matter had been developed in particular places in association with movements of limbs which were well supplied with skilled movements.

Professor FRASER also spoke.

The CHAIRMAN thought there was no description of the fissure of Rolando which fitted a majority of the cases which were studied. He believed that Professor Cunningham had himself become somewhat doubtful as to his former descriptions.

Dr. CRYMBLE replied.

Professor Symington and Dr. Crymble exhibited two specimens, one showing unilateral interruption of the fissure of Rolando, the other almost complete absence of the corpus callosum.

Professor Symington and Dr. J. C. Rankin showed a series of radiographs illustrating the development of the teeth. These beautiful and interesting exhibits were much admired.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, MAY 7TH, 1908.

The President, Mr. MARCUS GUNN, F.R.C.S., in the Chair.

EXHIBITS.

MR. E. E. HENDERSON showed microscopical sections from the case of orbital growth which was shown at the previous meeting.

Dr. EDRIDGE GREEN exhibited and demonstrated a lantern, of an economical design, for testing colour perception.

Mr. DEVEREUX MARSHALL highly approved of the lantern, which he understood would cost only 25s., as against about 6 guineas for the more elaborate lantern of Dr. Edridge Green.

Mr. **Nettleship** said he had used Priestley Smith's lamp, and found it very useful, patients making very few mistakes.

The **President** said he had had a lamp in use for 15 years, with ordinary red and green glasses, and an opaque ground glass, with a diaphragm.

Dr. **Clement Hailes** showed a portable illuminative attachment for the ophthalmoscope, which could also be used as a focal light. It was attached to a small accumulator, which could be carried in the pocket, leaving the hands free.

Mr. J. H. **Tomlinson** showed a Nernst lamp-projecting lantern for the consulting-room, also a small Nernst lamp in which the resistance was in the handle.

Mr. **Jessop** showed a case of aniridia of both eyes. Mr. **George Mackay**, Mr **Treacher Collins**, and Mr. **Devereux Marshall** described similar cases. Mr. **Jessop** showed a boy, æt. 9½, with glioma.

Mr. **Freeland Fergus** read a paper entitled

PTOSIS OPERATIONS.

The author first referred to the operations by sutures and ligatures, as illustrated by the operations of Mules, Harman and Worth. Attempts had also been made at advancement, as in his own method of advancement of the occipito-frontalis, and to attach a portion of the superior rectus muscle to the upper eyelid. Others had tried to advance the levator palpebræ superioris. Finally, there was the plastic operation, as in the well-known operation of Panas. The suture operations seemed in their essence bad; a thread which was absolutely sterile would not cause cicatricial contraction. Moreover, threads left projecting on the skin surface were apt to be channels of septic invasion. Ligature operations left the lid without much mobility, and success depended on the permanency of the metallic or tendinous suture. Of the advancement operations, he was satisfied with that of the occipito-frontalis. Recently, however, he had used a much larger incision than formerly. He now made an incision right along the eyebrow, and then continued it for 1½ to 2 inches upwards and outwards, so that he could reflect the skin very thoroughly. Where asepsis was secured, the patient was not disfigured with a scar in after-life. In many cases of ptosis, the levator palpebræ superioris did not seem to be developed at all. The eyeball was protected either by a Knapp's lid clamp, or by an ordinary metal spatula. A skin incision was made parallel with the edge of the eyelid and across its entire extent. It was situated a few m.m. above the free border of the lid. Another incision began at one end of the primary incision, curved upwards over the eyelid, and downwards, so as to terminate at the other end of the incision. The portion of skin thus isolated was then dissected up, and the tissue down to the conjunctiva removed. One set of sutures was placed deeply, consisting of one point in the middle, and one at either side. Superficial skin sutures were also inserted. For the deep sutures he used Van Hoorn's .00 gut. That operation lifted the eyelid easily to the required amount, and put it completely under the control of the occipito-frontalis muscle. Dr. Fergus showed a number of photographs of cases so treated, with excellent results.

Mr. **Priestley Smith** thought the question of most importance was what happened during sleep in cases which had been operated on; there might be considerable gaping of the lids.

Mr. **Roll** thought quite as good results were obtained from Hess's operation as Mr. Fergus got by his method.

Mr. **Marshall** thought that during sleep the eyeball rolled upwards, and that therefore the cornea would then be covered in any case.

Mr. **Fergus** replied. He said he did the first operation 12 years ago, and he had not yet seen corneal trouble. He believed that closure of the eyelid during sleep was involuntary. If he should encounter a case of ulceration of the cornea following the operation, he would consider it his duty to report it to the Society.

Messrs. E. **Clarke** and S. **Mayou** read a paper on

TUBERCLE OF THE IRIS TREATED BY TUBERCULIN.

In the case there was a large area of detached retina, forming a whitish prominence on the nasal side of the disc, 3 D, at the highest point, and crossing below the large inferior retinal vein. The retina in the upper part was covered with an exudate. There was no history of tubercle or syphilis in the case. The vision was 6/18, the vitreous full of opacities, and there was a mass of k.p. spots in the lower part of Descemet's membrane. A tumour was very distinctly seen, and as a result of a consultation with one or two colleagues, it was decided to ask Sir Almroth Wright to treat the case by tuberculin. That was done, and six months after commencing the treatment improvement set in, vision increased, and the k.p. spots disappeared, and the growth became flatter. The treatment was continued for a year, during which 21 inoculations were given, and the result was to drive the tubercle out of the system. The eye was now practically normal. Mr. Clarke next read a paper on "Confluent or Conglomerate Tubercle of the Iris Treated by Tuberculin." Except for hyd. cum. cretæ every night for a week on admission, and cod-liver oil, no other treatment was given. After needling, which he proposed to do later, the case was a complete success.

The cases were discussed by the President, Mr. Jessop, Mr. Herbert Fisher, Mr. Sydney Stephenson, Mr. Bishop Harman, Mr. Fergus, Mr. Johnson Taylor, and Mr. Cruise.

Mr. **Clarke**, in his reply, said the mercury was given, as he wanted to have a second string to his bow and avoid wasting precious time. He did not use Calmette's reaction, as he knew of a case in which inflammation of the eye had persisted for some weeks after its use.

Dr. **George Mackay** (Edinburgh) read a paper on a case of

ARTERIO-VENOUS ANEURYSM

treated by ligature of the common carotid artery. The author reported the result of a case shown by him at the Edinburgh meeting of the Society last year. The exophthalmos had now entirely disappeared, the bruit was no longer heard, and the vision now practically 6/18 in each eye. A month after the carotid had been tied, and while the patient was still in hospital, he developed thrombosis of the left leg and thigh, but he made a good recovery from that, and was discharged on August 2nd, and had since resumed his work as a coachman. Early last month he came to see whether anything could be done to remedy the convergent strabismus which remained as a result of the paralysis of the right external rectus. The power of that muscle also had improved considerably, and Dr. Paterson tenotomised the internal rectus, leaving only 5 degrees of convergence. He also read a paper on a case of phlyctenular keratitis and pustular episcleritis treated by antistaphylococcic injections. The patient at the age of 14 had keratitis in the left eye, with considerable impairment of vision, and five years later the other eye was affected, and she was under the care of Dr. Dufour, of Lausanne. His treatment was by hot fomentations, and anti-rheumatic powders internally. Shortly afterwards she consulted Dr. Mackay, and he found a small pustule on the right conjunctiva, which had discharged its contents and appeared as a raised ulcer. There was a haze in the cornea and a thinning in the ciliary region, but no pain. Hypermetropic astigmatism was present in both eyes, but she had not worn glasses. He ordered weak yellow oxide of mercury ointment, with atropine, and grey powder and bicarbonate of soda internally, followed by an arsenic and iron tonic. Under this she gradually improved, and correcting glasses were ordered. Three years later she returned with a small patch of injection in the edge of the right cornea, and there was a fringe of older opacity in the position of the arcus senilis. The same treatment again produced improvement. Subsequently there were several recurrences, and in August, 1906, he suspected the cause was tubercle, especially as her parents had been related before marriage, and she had some phthisical relations. Dr. Ian Stewart, at his request, took the opsonic index, and it was found to be for tubercle 0·74, and for staphylococcus aureus, 1.24. Films from the conjunctival sac showed large numbers of polymorphonuclear leucocytes, and a few staphylococci, but no tubercle bacilli. Dr. Stewart thought the condition was not tubercular. After a week antistaphylococcic treatment was started, 1/55 mg. of dried staphylococcus aureus being given, dissolved in 1 c.c. of distilled water. The following day there was a decided negative phase, the index falling to 0.92, but 24 hours later it had risen to 1.86. Steady improvement set in, and in January this year she said she was very well, and had kept so. The general aspect of her eye was much improved. He proceeded to discuss the ætiology of the episcleritis, and to bear testimony to the great value of the opsonic index, particularly in distinguishing tubercular from staphylococcic infection. He laid stress on studying the positive or negative phase 24 hours after an injection. He believed the first suggestion of diagnosis by giving small doses of dead bacilli was made by Drs. Lawson, of Banchory, and Ian Stewart, of Edinburgh, in the "Edinburgh Medico-Chirurgical Transactions, 1905."

Mr. **Jessop** discussed the case, and Dr. **Mackay** replied.

ROYAL SOCIETY OF MEDICINE.

Therapeutical Section.

Meeting held Tuesday, April 28th, 1908.

The President, Dr. **Burton Brown**, C.I.E., in the Chair.

Dr. **Leonard Guthrie** read a paper upon

RHEUMATISM AND CHOREA IN CHILDREN.

He maintained that salicylate of soda and allied drugs were palliatives, but not cures, for rheumatism. Carditis and nodules appeared in patients fully under the influence of chorea. The use of large doses of salicylates was not devoid of danger. It was contended that sodium bicarbonate was an antidote to the poison of salicylates, but to give poison and then antidote at the same time was a questionable therapeutic measure. The treatment of the acute stage of chorea was by rest in bed, quiet, isolation, protection from injury, nourishing food. In severe cases hypnotics were necessary—chloral and bromide, chloralamide or chloretone. Arsenic, given on the intensive method, was not recommended. Ill results in the shape of gastro-enteritis and peripheral neuritis were too frequent. Salicylates, including aspirin, could not be regarded as curative. The average duration of chorea, under the mode of treatment recommended, did not exceed four or five weeks, and cases which did not recover under three months could not be considered testimonials to any form of treatment adopted.

Dr. **Cecil Wall** said that with almost all that Dr. Guthrie had said he felt himself in complete accord. Referring to statistics, published in the "Transactions of the Therapeutical Society for 1905," which he had compiled in an attempt to estimate the effect of different drugs in chorea, Dr. Wall stated that he then found that, of cases treated by arsenic, 38 per cent. were cured in less than two months. Similar figures were given for treatment with salicylate of soda, and with other drugs. It was only when they came to the treatment with aceto-salicylic acid that they found a very marked difference. Of these 92 per cent. were discharged from hospital in less than two months, the majority in four weeks from admission. After two more years' experience of this treatment, he still felt very strongly in favour of it. With regard to the dangers of the use of aspirin—the vomiting to which Dr. Guthrie had alluded—he found that it was possible to avoid that altogether if aspirin was only given when there was food in the stomach. Moreover, aspirin should never be given in tabloid form, but invariably as a powder. Very large doses—doses such as he himself would not prescribe—he had seen give rise to hæmaturia. In violent cases he thought it wise to make use of sedatives, and he would select chloral and chloralamide. He thought the use of bromides very harmful. In certain cases the result of giving bromides had been to produce mania. Any depressing drug like bromide was liable to exaggerate rather than ameliorate the condition. He looked upon chorea as being due to a paralysis of the cortical centres allowing the lower parts of the nervous system to act spontaneously.

Dr. D. B. **Lees** maintained that the neurotic element in chorea was probably the effect of the rheumatic toxin on the brain. He laid emphasis on the alteration in temper and disposition which was often manifested in children with early chorea. At times, too, there was very distinct aphasia, more than could be accounted for by simple weakness of muscular movement. Lastly, hallucinations of vision were not infrequently met with. In the treatment of rheumatism and chorea, he advocated the use of very large doses of salicylate of soda. He believed very strongly that salicylates were more readily tolerated if a double dose of sodium bicarbonate was given at the same time. When unpleasant symptoms occurred, the dose should be decreased, not omitted. Given in this way, it was usually possible to educate the patient to tolerate without difficulty three or four times the dose which at first caused unpleasant symptoms. He had found such extraordinary benefit result from the local use of ice in pericarditis, that he was surprised to hear Dr. Guthrie say that he gave opium in pericarditis because he did not know what else to do.

Dr. **Gordon Sharp** said that he had never found that depression resulted from the use of salicylates, and he agreed with Dr. Lees that large doses did great good. He was much astonished that opinion in London was against the use of arsenic in chorea. His own experience in the North of England was that it was a most valuable drug. He thought that there must be something peculiar in the London constitution that could not stand that important drug. He believed very strongly that there was an intimate connection between rheumatism and chorea.

Dr. J. **Gray Duncanson** spoke of the success which attended the use of arsenic in chorea in Scotland. He thought that it was all a matter of environment.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held May 6th. 1908.

The President, Dr. **James Ritchie**, in the Chair.

Dr. T. D. **Luke** demonstrated a new dropper for ethyl chloride, made by Messrs. Bransom and Co., Leeds, and an open ether mask, by which it was possible to anæsthetise a patient as easily, and with as little ether, as with a Clover's inhaler. For robust or alcoholic patients, however, a closed inhaler was preferable, unless an injection of morphia was given prior to the administration of the anæsthetic.

Professor **Chiene** described a simple method of preparing catgut, and showed several appliances for conveniently demonstrating auto-chrome transparencies without a lantern. They consisted of carriers for lantern slides, some with magnifying arrangements, suitable for handing round to a class of students.

Dr. **Melville Dunlop** read a paper on "Some Considerations regarding Pneumonia in Children drawn from an analysis of 500 cases." (A full abstract of this paper will be found on page 555.

The paper was discussed by Dr. **James Carmichael**, who urged the value of atropine in pneumonia; by Dr. **Russell**, who dilated on the pathology of the disease, and pointed out that histologically and bacteriologically there was little or no distinction between lobar and broncho-pneumonia; and by Dr. **Playfair**, who said that he thought that cough mixtures were frequently of service, and that he did not hesitate to give small doses of antipyretics if he was anxious about the temperature. Dr. **Thomson** referred to the recurrence of pneumonia in the same patient, and to its occurrence in families. He spoke of the usefulness of Dover's powder as a sedative, and of the efficacy of treatment in the open-air in some cases.

The paper was also discussed by Drs. Fowler, W. B. Drummond, Geo. Hunter, Cowan Guthrie, and the President.

Dr. Douglas Argyll Robertson and Dr. J. Hughlings Jackson were elected honorary members of the Society, and the following gentlemen were elected corresponding members:—Ivan P. Pavloff, St. Petersburg; Sir Henry Swanzy, F.R.C.S.I., Dublin; Francis J. Shepherd, F.R.C.S.E., Montreal.

LIVERPOOL MEDICAL INSTITUTION.

At the Last Meeting held,
Mr. T. H. **Bickerton**, F.R.C.S., President, in the Chair,

The following cases were brought forward:—

Mr. **Colin Campbell** read notes of a case of "abscess of the lung" following pneumonia, successfully treated by intra-tracheal injections of Izal. Mr. Campbell exhibited the patient, a male, æt. 42, who had been placed under his care by Dr. McNair, of Manchester. The illness commenced with an attack of acute pneumonia on July 17th, 1907. On the 14th day a large quantity of pus was expectorated and the acute symptoms were relieved. Pus continued to be expectorated freely, empyæma was diagnosed, but exploration failed to find pus. His condition remained the same until October 29th, when he commenced the Izal injections. He was bringing up 10 oz. of pus daily. At the end of a week he was taking 2½ oz. of 10 per cent. Izal solution at each daily sitting.

On December 16th he discontinued treatment, cured, having gained 21 lb. He has remained well since and follows his usual occupation.

Mr. **Rushton Parker** related cases of completion of union by "bone implantation" in un-united fracture. His method is to graft small pieces of bone removed from the un-united fragments between the ends, after removing all unossified material from between them. He considered that in confirmed non-union we have, by planting minute grafts of living bone between the bared ends, a means of procuring re-union both easier and less deforming than by wiring or other methods of suture, and less dangerous. Radiographs were shown to illustrate the gradual increase of density of the callus.

CHRONIC COLITIS, WITH SPECIAL REFERENCE TO PERICOLITIS SINISTRA.

Dr. J. **Lloyd Roberts** read a paper on this subject. He expressed the opinion that this affection is more common than generally thought and deserved more attention. Pericolitis might occur in acute or chronic form.

The acute was usually circumscribed, and arose from ulceration of the mucous membrane of the colon, which might be stercoral, traumatic, tubercular, dysenteric, typhoid, or malignant in character. It spread through the walls of the bowel and led to circumscribed tumours outside and in contact with them. These tumours had often been mistaken for malignant growth. Occasionally the inflammatory product spread round the bowel and caused obstruction. These tumours were capable of resolution under appropriate treatment, as occurred in two cases of which details were given. Occasionally they suppurate and form abscesses which burrow along the length of the bowel. Two cases were mentioned in which abscesses were diagnosed and opened, one near the splenic flexure and one in relation to the iliac colon. Rarely peritonitis might occur from bursting of the abscess or extension from the underlying ulcer.

The chronic form was usually diffuse, and arose from spread of inflammation from neighbouring organs or the mucous lining of the bowel. The latter form, where the inflammation infiltrated through and involved all the coats of the bowel, generally occurred in the ascending colon or the iliac colon. The latter situation is most frequently affected, and the disease has been known as perisigmoiditis or pericolitis sinistra. Of this form Dr. Lloyd Roberts had met with nine cases, 4 in men and 5 in women—six of the nine occurring between the ages of 21 and 26. The clinical history and the physical signs were described. He showed that they were all preceded by long continued constipation, with retention of fæces within the colon. The fæcal masses became dry and rough, and set up irritative colitis. The walls became distended and pouches and diverticula were formed. All the layers of the walls became infiltrated and lymph deposited on the serous surface. This tended to form adhesions to neighbouring structures, and sometimes caused obstruction. In the early stage the bowel, when emptied, felt firm and of less diameter than normal, and was easily rolled about. This is the hypertonic or spastic type. Later on the muscular coat lost its tone and the bowel felt like a thick ribbon, with still thicker edges, soft and doughy to the touch. This is the atonic stage. Cases illustrative of the various types were described, and a portion of iliac colon removed from one patient by Mr. Newbolt was shown to confirm the changes above described. In discussing the pathology, Dr. Roberts suggested that the cause lay in a late origin and narrowness of the mesentery of the pelvic colon, owing to which the bowel became kinked near the bony brim of the pelvis. The medical treatment consisted of administering intestinal antiseptics, external application of mercury and belladonna, and, most important of all, daily douching of the colon with hot antiseptic douches, which should be persevered with for many weeks. Patients should be warned of the risk of recurrence should constipation again occur.

Dr. A. G. **Gullan** confirmed the statement that pericolitis sometimes resembled malignant disease, and quoted a case in point. He considered the pain of colica sinistra was usually definitely localised over the sigmoid or ascending colon, and in only very rare instances was the pain diffuse.

Mr. **Keith Monsarrat** considered that the worst cases of infiltrative colitis required some form of surgical treatment which gave rest to the affected part. Without this they tended to persist indefinitely. He considered that the suppurative and adhesive types of pericolitis required surgical treatment.

Dr. **Blair Bell** drew attention to pelvic peritonitis in women as a cause of pericolitis. Of the last 500 cases seen by him in the gynæcological out-patient room, 22 per cent. had pain in the left iliac fossa, and in one-third of these the cause had been ascribed to chronic constipation, with trouble in the pelvic colon. In cases of abdominal section he was surprised to note how many had adhesions around this part of the bowel, either from intrinsic or extrinsic causes.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, May 17th, 1908.

Treatment of Eclampsia

Eclampsia is not a malady. It is rather a clinical syndrome representing one of the forms of gravid intoxication. What should be specially borne in mind is that the treatment should be directed both against the exciting cause and the effect—that is to say, the convulsive attacks and coma produced by reaction of the central nervous system under the influence of toxins which have not been, as yet, either isolated or defined.

It is rare that convulsions set in suddenly; more frequently they are preceded for more or less time by other symptoms, as vomiting, ptyalism, irritability of temper, neuralgia, etc., but the most frequent of these manifestations is albuminuria. Consequently, for a very long time eclampsia was considered a complication of albuminuria. Recent urological studies, however, have proved the independence of these two affections, eclamptic attacks having been observed in women whose urine was free from any trace of albumin.

The prophylactic treatment of eclampsia should be based principally on the *régime* which all pregnant women should follow, to avoid auto-intoxication, and this *régime* should be particularly severe in the presence of albuminuria, and consists in absolute milk diet, rest in bed, repeated purgatives, and daily examination of the urine as regards both quantity and quality.

Where premonitory symptoms of eclampsia, accompanied or not by albuminuria, are observed, the milk should alternate with Evian water, a glass of one or the other every one or two hours; an ounce of lactose might be added to each bottle of Evian water. Besides rest and purgatives, a large enema of boiled water should be given every night, while 20 or 30 grains of chloral should be taken in some diuretic infusion.

If these premonitory symptoms become aggravated in spite of this treatment, a pint of blood should be taken from the arm.

When convulsions have set in, the treatment must be more active. Care should be taken to remove any false teeth if present, and a handkerchief should be placed between jaws so as to prevent the tongue from being bitten. The bladder should be emptied by means of a catheter, and the patient watched so as to avoid a falling out of bed. The medical treatment consists in administering chloroform during the duration of the seizure, and an enema of 1 drachm of chloral in milk and the yolk of an egg. If the patient is in coma, only water should be given as a drink, and the patient freely bled, a quart or more according as the pulse may permit it.

An important question presents itself—should delivery be provoked or should Nature take its course?

Forced delivery has been recommended and practised, but the results do not appear to have been favourable to the patient.

In the case where labour has commenced spontaneously, either during the attack or within a few days after, severe antiseptic precautions should be taken, as eclamptic patients are particularly predisposed to infection.

The best antiseptic is formol:—

Formol, 2 dr.
Sulphate of copper, 1 dr.
Ess. of geranium, ½ dr.
Proof spirit, 8 oz.

A tablespoonful for two quarts of boiled water given as injection.

As soon as the os is sufficiently dilated, delivery might be hastened, if necessary.

As hæmorrhage is not rare, particular attention must be paid to the patient during the first few days after delivery.

The milk diet must be maintained as long as albumin is found in the urine, and that the patient does not secrete more than a quart of urine in the 24 hours.

Such is the method of treatment adopted by Dr. Rudaux.

MILK DIET.

Milk diet presents its indications at each turn in medical practice. Yet many practitioners, says Prof. Surmont, complain of the difficulties of getting it accepted by their patients, who pretend to be unable to support it.

It is important to understand that many patients are only refractory in appearance to milk diet, and ill-support it because they do not know how to take it in a suitable form.

The maladies for which the milk *régime* is indicated may be divided into two groups—acute and chronic affections.

The utility of milk diet in acute diseases is patent, whether it concerns general infections, where renal complications are possible, as eruptive fevers (scarlatina, typhoid, spotted fever, septicæmia of divers origin, or in those affections in which phenomena of intoxication are predominant, as diphtheria, tetanus tonsillitis, pneumonia, cystitis, acute nephritis, uræmia, hepatic insufficiency and eclampsia.

It must be remembered that in acute febrile affections, digestive secretions are reduced, and consequently the susceptibility of the digestive tract must be taken into account before prescribing large quantities of pure milk.

Wherever digestive fermentation is well marked with a furred condition of the tongue, a saline purgative and a purely hydric diet should precede by 24 hours the ingestion of milk.

It is especially in chronic affections of the digestive tract, liver, heart, kidneys, urinary organs, skin and such intoxications as mercurial, saturnine, and certain auto-intoxications (uræmia), that the milk diet has given considerable therapeutic results.

In chronic maladies it is of the highest importance that milk be well tolerated by the digestive tract, since, in order to produce the desired result, its employment must be prolonged for weeks and months.

In certain dyspeptic patients, and especially those who present well-marked butyric fermentation, the milk, as soon as it arrives in the stomach, becomes decomposed and provokes tympanism, acid regurgitations, pain, vomiting, or diarrhœa—all the symptoms of indigestion.

Patients who have suffered from these troubles acquire a repugnance for the *régime* and refuse it absolutely. A previous disinfection of the stomach by a purgative and hydric diet (Vichy water) will prevent these accidents.

Should the milk be given in its natural state or boiled? As regards the question of digestibility, the former is more easily digested, it is certain, but, on account of the frequency of bovine tuberculosis, it is always safer to boil the milk before taking it unless its origin is certified. In any case, in towns boiled milk only should be prescribed.

As regards the quantity of milk to be absorbed in the day, the average would be about four quarts, but this amount is not easily tolerated by patients, who can scarcely consume more than three quarts, and frequently less. A glass of milk every two hours, or three pints a day, is the best way for a beginning. Afterwards the dose might be increased to double that amount as the patient may tolerate it.

It is important that each glass of milk should be taken by sips every two or three minutes, and not all at once, which might produce a large clot of casein, a frequent cause of indigestion. Hot milk should be preferred, as it is absorbed more readily, but when there is a tendency to vomiting, cold milk is more suitable.

The mouth should be rinsed with some alkaline water, Vichy or Vals, for instance, after each little repast, to prevent the accumulation of the residue of milk in the mouth, which ferments and develops inflammation of the mucous membrane of the cavity, as well as fœtidity of the breath.

Some patients show a complete disgust for milk which a little persuasion overcomes. The savour, in any case, can be masked by the addition of a little tea, coffee, chocolate, sugar, salt, seltzer water, cherry laurel water, or different liquors, Kirsch, rum, cognac, when the employment of these different substances is not contra-indicated.

Certain patients present an absolute gastric intolerance for milk (furred tongue, fœtid breath, gastric heaviness, palpitations, vertigo). For these the cream should be carefully removed, and lime-water or Vichy water given with the milk. Where diarrhœa is provoked by the milk *régime*, it is due to the coagulation of the liquid in an hyperacid stomach. In such cases milk and alkaline water should be given in equal parts, or the milk should be sterilised.

It sometimes happens that, in spite of all the precautions observed, cows' milk is not tolerated. Recourse must be had to asses' milk or kephyr. The former contains more sugar or lactose than cows' milk, but is less rich in albuminoids and fatty matter. It is less nourishing, but being more easily digested, it is particularly suitable for weak stomachs. However, it is difficult to obtain in towns.

A better method consists in utilising kephyr, which, as everyone knows, is composed of cows' milk subjected to special fermentation due to the combined action of a yeast and a microbe, *dispora caucasica*.

Under their influence, the lactose gives lactic acid, alcohol, and carbonic acid. The casein, precipitated, undergoes a primary digestion, transforming it into peptone.

Kephyr is an acidulated and sparkling drink.

The ferment can be bought in grains and added to the milk at a known temperature, but there exist special kephyr manufactories which give every guarantee of a pure article.

GERMANY.

Berlin, May 17th, 1908.

At the Verein für Innere Medizin Hr. Albu reported

Two Cases of Poisoning.

The first was one of poisoning by corrosive sublimate. Two grammes had been taken, and the clinical symptoms produced were remarkably slight. Hæmorrhagic diarrhœa appeared for the first time on the third day after the poisoning, then vomiting came on, the patient dying of exhaustion on the tenth day. The stomach showed the typical picture of diphtheritic inflammation; the whole of the small intestine was free from pathological changes, the most serious being in the large intestine; these consisted of necrotic patches, but they did not penetrate to the serosa. The kidneys showed the typical changes, acute nephritis with fatty degeneration.

(2) Carbolic acid poisoning. It was the case of a young girl who had attempted suicide on account of a love affair. The speaker did not see the patient until seven weeks after the poison had been taken; she complained of gastric troubles. There was a typical stenosis of the pylorus with an-acidity. Gastroenterostomy was performed. There were necrotic patches in the superficial layer of epithelium of the interior of the stomach.

Hr. Boenninger spoke on

Renal Diabetes.

He said that in diabetes mellitus the glycosuria depended on an increased quantity of sugar in the blood, hyperglycæmia. Glycosuria had now been repeatedly observed in men whose sugar constituent had not been increased, had been diminished even. For these glycosurias the cause must be sought in the kidneys themselves, they went by the name of renal glycosurias. By a few authors the occurrence of such cases had been disputed (von Noorden). The uncertainty regarding the subject depended on the difficulty of estimating the quantity of sugar in the blood. The speaker considered it necessary to examine, not the whole of the blood, but only the blood serum, as the blood corpuscles contained far less sugar, at least, as a rule. A correct estimate of the sugar in the serum would not be reached by an examination of the blood as a whole. On the other hand, as regarded the excretion of sugar by the kidneys, it was only the sugar contained in the serum that had to be considered. He had determined the normal sugar constituent of blood serum to be 0.09 = 0.10 per cent.

In renal diabetes it was desirable further to be independent of the carbo-hydrates. The speaker described such a case in which 0.1 to 0.5 per cent. of grape sugar was excreted daily. The glycosuria could not be influenced by the strictest diet, nor by a large allowance of carbo-hydrates. These cases were of great importance as regarded practice. Even if they seemed to appear only rarely it was important for the physician to recognise them, for it would be a needless torment and also very injurious to deprive such a patient of carbo-hydrates in his dietary.

Hr. Mohr was of opinion that the sugar constituent of the blood and the excretion of sugar did not run on parallel lines, the criterion of the normal sugar constituent of the blood was very uncertain. In order to differentiate between renal and ordinary diabetes, he proposed to examine the gaseous changes in respiration. If a large meal of albumen was given to a healthy man and the respiratory gas changes were examined every hour or every two hours afterwards the following would be noted:—The respiration quotient mounts rapidly and reaches its maximum of about 0.8 from two to four hours after the meal. In the latter hours it falls, and at about the eighth nearly reaches the hunger value. In the diabetic it was different. Corresponding to the greater or lesser excretion of sugar that takes place after the meal the respiration quotient at first sinks very low—below 0.7—rises again between the sixth and eighth hours, or later still, and then reaches its full value for the digestion of albumen. The reason for this was that the diabetic burnt sugar, but more slowly than the healthy man; hence the rise of the respiratory quotient. He suggested that the gaseous test should have a trial in some case of the kind.

Hr. Magnus Levy thought that, in addition to an abnormal permeability of the kidney for sugar, there was also an active renal diabetes, as was shown by the action of phloridzin. Pavy had given expression to the notion that under the influence of phloridzin the kidney secreted grape sugar as the mammary gland secreted milk.

Hr. Bleichroeder stated that in lying-in women who excreted milk sugar in the urine the sugar constituent of the blood was diminished by about one-half.

Hr. Felix Hirschfeld pointed out that the patient in Boenninger's case was an alcoholic. The changes in the liver and kidneys in alcoholics frequently caused a diminution of the glycosuria and perhaps in that way the absence of connection between the glycosuria and carbo-hydrates was explainable.

Hr. Boenninger, in reply, said that in his case he had always obtained a filtrate free of albumin. After giving large quantities of grape sugar he had performed venesection some hours later and had always obtained a low value. The serum must be examined, the sugar contained in the blood corpuscles did not count as far as the kidneys were concerned.

AUSTRIA.

Vienna, May 17th, 1908.

Orthostatic Albuminuria.

This subject is now monopolising every meeting of the "Gesellschaft der Ærtze." It was introduced in the form of a paper on the subject by Stejskals, which has excited a considerable amount of interest. Escherich thinks this form of albuminuria is very common in children, and asks how this can be reconciled with the erect posture. He had devoted some time to the hypothesis of Jehle that this morbid change in the urine in the erect position was entirely due to a lordotic bending of the spinal cord and therefore mechanical in its origin by disturbing the vascular circulation of the kidney, and was finally driven to the conclusion that there was some truth in the suggestion. He found, as Jehle, that when the orthostatic or upright position was assumed in the lordotic subject albumin was found in the urine. As soon as the lordosis was corrected the albumin disappeared, in any position. This surely points to a close connection of lordosis having something to do with the abnormal product, but whether the lordosis is a normal or pathological agent is another factor to be considered. His own opinion was the lordosis produced a congestion in the venous circulation of the organ with an albuminous result.

Strasser said he had found by experiment that the renal reflex was more sensitive than in any other organ of the body, therefore, he says two causes for the albuminuria may be found, viz., ischæmia and stasis. A simple hyperæmia is not sufficient of itself to produce albuminuria, but if a loss of tonus be associated with this in the renal vessels albuminuria is established. Innervation, therefore, may accompany the congestion. Stejskals is inclined to believe in the arterial path being interfered with rather than the venous, but was not sure if a nephritis previously existed.

Gerber bore testimony to Jehle's theory being the correct solution of this morbid product being in the urine.

Kapsammer was not pleased with such theories, and believed that a form of nephritis was the real cause of the albuminuria. Nephritis might be divided into primary and secondary. Secondary nephritis was an anatomical lesion following a neoplasm, stone, wandering kidney, or hydronephrosis, and primary when nothing but cold or exposure could account for the lesion. Now, is it possible to have unilateral primary nephritis? Kapsammer asks and answers it himself in the affirmative, as he has often met with this condition where the urine from one kidney is quite free from albumin, while that from the other is loaded with albumin. This he proved by giving floridizin. When we, therefore, meet with a case of orthostatic albuminuria we may expect a parenchymatous lesion. This parenchymatous lesion may exist without the functional disturbance of the erect posture, which we may look upon as an accident in a case of parenchymatous nephritis where no cylinders are met with in the urine, but simply albumin. With this explanation, orthostatic albumin is only a symptom, and not a disease *sui generis*, separate from nephritis, or what may be termed an inferior condition of the kidneys, which may have its origin in a pure mechanical irritation or a nervous reflex condition. In any case, we cannot separate this form of albuminuria from nephritis.

Schur thought it waste of effort to speculate on the disease when we could not exactly tell yet how albuminuria was produced. We were still without any exact evidence on the subject and therefore unable to approximate the cause.

Chvostek believed in the reflex vascular innervation. Jehle tells us the albuminuria is due to lordosis; but what is the cause of the lordosis? Is it not the same cause that produces the lordosis that excites the albuminuria? Both are under the same influence. Doubtless, there is some change in the kidney itself or its vessels, but how the morbid condition is brought about we cannot say, as it varies in different individuals. About puberty the secretions of all the organs are changed by a nervous influence, hard to explain. In orthostatic albuminuria the adrenalin secretion may have increased the gland and surrounding adnexa that may interfere with the functional activity of the kidney, and thus produce albuminuria in the same manner that pregnancy does. Novak recorded the history of 14 cases of orthostatic albuminuria which gave a similar result to Jehle's. He obtained the albumin not only when standing but in other positions, such as suspending the body, raising the legs and twisting the arms in different directions. Compressing the thorax and bandaging the limbs had the same effect. He suggested a twisting of the ureters or other pressure on the vessels might have the same effect. As to the lordosis being the true cause, he thought the anatomy of the organ was against it. In some of his cases no lordosis existed and yet the orthostatic albuminuria was present. There was a distinction made between passive and active lordosis in the production of the albumin. The former mechanism was when the spinal muscles were feeble and lax, the latter was the opposite condition when albumin was absent. In his own experiments he could not make this distinction.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Edinburgh Royal Maternity Hospital.—At the annual meeting, held on May 14th, it was stated that the in-patients for the year numbered 464, and the cases treated at their own homes 825. Just half of the intern cases were married women. The number of nurses trained was 57; in order to meet the requirements of the Central Midwives Board in respect to the number of cases a nurse must have under her own supervision, a branch of the hospital has been opened in Leith. Seventy students have been enrolled, as compared with 87 last year. During the year the hospital has received, as a memorial of Emeritus Professor A. R. Simpson, a gift of money to found a ward to be named after him. References were made to the loss the hospital had sustained through the deaths of Professor Annandale and Dr. Underhill.

Edinburgh Medical Appointments.—Considerable comment has been aroused by the comparatively small salaries offered for the posts of divisional police surgeonships, and in one division it is stated that there have been no applicants for this reason. It is understood, however, that appointments have been made in four of the divisions. The Public Health Committee recommend the appointment of a medical woman to act under the Notification of Births Act at a salary of £120 per annum. More important so far as the health of the city is concerned, however, does it seem to us that the salary fixed upon for the Medical Officer of Health is "not less than £800" per annum. To attract a first-rate man a higher bid ought to have been made, and it is to be hoped that the figure offered will be increased to £1,000.

BELFAST.

Cerebro-spinal Meningitis.—Though there is nothing like the epidemic of this fever which there was a year ago, there are still a few new cases every week. Three cases were admitted to the Purdysburn Fever Hospital last week, and three the week before, and 13 cases are under treatment in hospital. No doubt there are some being treated at home, as there has been a growing tendency to keep the cases at home since the fever has proved to be not markedly contagious. In the treatment of the hospital cases Flexner's serum is still being used with most satisfactory results.

Women's National Health Association.—The local branch of the Women's National Health Association has formulated what appears to be a very excellent plan for assisting in the anti-tuberculous campaign. They propose to engage the services of a specially trained nurse, and employ her in visiting consumptives, and specially those who have been discharged from hospital. Her duties will not be so much actual nursing as instruction in hygienic matters and putting the patients in the right way of living in their own homes. The medical men of the city will certainly wish the movement every success.

Election of Poor-Law Guardians.—A strong effort is being made to increase the number of lady guardians on the Belfast Board at the forthcoming elections. For several years there have been two or three ladies on the Board, and now, under the auspices of the Society for Brightening Workhouse Infirmary Life, there are six candidates going to the poll, while one has been returned unopposed, the wife of a medical man. The work hitherto done by the lady guardians in Belfast has been most beneficial to the workhouse and its inmates, as well as to the ratepayers, and they have worked, as a rule, in complete harmony with the medical attendants.

LETTERS TO THE EDITOR.

THE POPULATION QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your valuable paper this week "Veritas" discusses the question of the "Marriage of the Unfit," and the duties of the profession in view of the recklessness with which many of these unions are brought about. This question is important, but sinks into almost complete insignificance in presence of the new development of the population question as a whole. Within the past few days there have been published the quarterly returns of the Registrar-General, and these show once more the lowest birth-rate on record. If this fall continues at the present rate, in a very few years the population of these islands will have become stationary in numbers, so that, unless a change speedily takes place, the decline and fall of the British Empire will soon be well in sight, without the aid of the prophet's telescope or any scientific demonstrating apparatus. The last census showed that the whole Empire, including India, contained only 55,000,000 of people of European blood. The birth-rate in most of our colonies is falling as rapidly as that at home, and we shall in a few years have no men to send to these vast domains, three of them—Canada, Australasia, and Africa—being each equal in extent to Europe, and each capable of supporting in time populations of hundreds of millions. In the meantime, Germany has 64,000,000 at home, besides at least a few more millions in her colonies, and in other lands, who still retain their attachment to the Fatherland, and her population is increasing by nearly a million a year. France, whose pernicious example we have copied, makes no increase; she remains at 38,000,000, *plus* a few hundred thousand more or less really naturalised Swiss, Italians and Germans. Without allies she would be at the mercy of Germany. The French are always declaiming about their patriotism, and yet the whole people, with very rare exceptions, although fully aware that their safety and existence as a free nation depend upon it, refuse to make what they regard as the sacrifice involved in rearing a family of more than two or three children. The motive is not prudence—the wealthiest and the best educated are the worst offenders—but pure egoism, the cult of ease and luxury. The French are a decaying race, in spite of their magnificent gifts; and the same will soon be said with justice of the British. The example of restricting the number of the children has been set by the wealthy and well-to-do, not by the poor, who might plead some justification; and it is one sign among many others of the moral decay of this erstwhile mighty people. The nations of to-day, if they go to ruin, will go with eyes open. Every man of intellect can see whither the vices of civilisation must lead; and if the people will not listen to the latter-day prophets who reason from the basis of scientific fact, as well as from the testimony of history; if they will not listen to the preachers who exhort them to strive for high ideals, nothing seems possible to save them from the doom which from similar causes overtook all the not less mighty peoples of antiquity.

I am, Sir, yours truly,
A Student of Sociology.

LAW FOR LAWYERS AND LAW FOR DOCTORS.

To the Editor of The Medical Press and Circular.

Sir,—The *Times* this morning furnishes another illustration of the fact that it is impossible for an unqualified solicitor to exist under any pretence. At the East Ham Police Court yesterday, May 15th, a man was fined £2 and costs for "falsely pretending to be a solicitor." He had used no professional title, and had merely written a debt-collecting letter with words which a lawyer's intellect, but hardly any other, might construe into the false pretence alleged against him. On the other hand the papers this week have reported the case of an unqualified quack committed for trial for felony who has been practising for years as a doctor, and using full professional titles. No attempt had been made to interfere with him under medical law, and it had not been made, first because it was more than doubtful whether a conviction was possible, and secondly, because their exists no authority like the Law Society charged with the duty of putting the law in force. The responsibility, and the shame, of the present state of things, the degraded position of the profession in relation with the State, and the unchecked plunder and maltreatment of the poor and simple suffering classes, rests upon the profession. They alone know the facts; they alone are in a position to force them upon the attention of the Legislature.

I am, Sir, yours truly,
An Obscure Practitioner.

May 16th, 1908.

OBITUARY.

CHARLES JAMES CULLINGWORTH, M.D., D.C.L., LL.D., F.R.C.P.

It is with much regret that we announce that Dr. C. J. Cullingworth died on May 11th. Born in Leeds in 1841, he was educated at Wesley College, Sheffield, and afterwards studied for his profession at the Leeds School of Medicine. He was admitted a member of the Royal College of Surgeons in 1865, and afterwards was in general practice in Manchester. He early secured the appointment of medical officer to the C and D Divisions of the city police force, posts which he held for some time. He applied himself to a study of the diseases of women, and obtained a name for himself in this branch of medical science. In 1879 he was appointed lecturer in medical jurisprudence at Owens College, a position which he held till 1885. In that year Dr. Thorburn, who was Professor of Obstetrics and Gynæcology, died, and Dr. Cullingworth was chosen to succeed him. In the meantime—in 1878—Dr. Cullingworth had joined the staff of St. Mary's Hospital, Manchester, where his work was highly valued.

In 1888 Dr. Cullingworth severed his connection with Manchester. The post of senior obstetric physician at St. Thomas's Hospital, London, became vacant, and it was offered to Dr. Cullingworth and accepted. Dr. Cullingworth fully justified the choice which was made, and for sixteen years he laboured with signal success to maintain the reputation of the hospital. He retired from the post he had so ably filled in 1904. Dr. Cullingworth held a number of public appointments in medicine. He was an examiner of the University of London from 1890 to 1895, and of the University of Cambridge from 1896 to 1900; chairman of the Board of Examiners for Midwives of the Obstetrical Society of London in 1895 and 1896, and in the following year was elected President of the Obstetrical Society. He was Bradshaw Lecturer of the Royal College of Physicians in 1902, and Ingleby Lecturer at the University of Birmingham in 1904. Dr. Cullingworth wrote largely on questions connected with his special department of medicine. Among his works were:—"Puerperal Fever, a Preventible Disease"; "Charles White, a Great Provincial Surgeon and Obstetrician of the Eighteenth Century"; "Oliver Wendell Holmes and the Contagiousness of Puerperal Fever"; and numerous articles and papers on gynæcological subjects. Dr. Cullingworth was an enthusiast in his work, and everything he did was marked by thoroughness, patience, and close observation. His relations with his students both in Manchester and London were of the most cordial nature, and by those who had the advantages of studying under him he will be remembered as a clever and genial teacher.

He received the honorary degrees of LL.D. of Aberdeen and D.C.L. of Durham.

THEODORE DUKA, M.D. St. And., M.R.C.S.

We regret to record the death of Dr. Theodore Duka, at Bournemouth, in his 83rd year. Dr. Duka was by birth a Hungarian of noble family, and in early life played an active part in the political and military vicissitudes of his country. He was aide-de-camp to General Arthur Görgey, and at the battle of Komoru on April 26th, 1849, he was decorated on the field with the Order of Valour for a conspicuous act of courage. He also received promotion for his conduct at the siege of Buda. When the Hungarian forces finally surrendered at Villágos on August 13th, 1849, to the Russians, Dr. Duka became a prisoner of war; but he finally escaped and, after a long series of adventures and wanderings proceeded to London in 1850. Here he decided to adopt the profession of medicine, and for the rest of his career identified himself with the country of his adoption. He had previously studied at St. George's Hospital, of which in later life he became a governor, and in 1853 he had taken the degrees of M.R.C.S. (Eng.) and M.D. (St. Andrew's). In 1854 he obtained a commission on the medical staff of the Bengal Army, and in 1856 he was stationed at Monghyr and was there throughout the Mutiny. He retired from the service in 1877 with the military rank of lieutenant-colonel. Dr. Duka, who finally settled in London, was chairman of the Austro-Hungarian Aid Society here. He also for many years took a keen interest in the British and Foreign Bible Society, and had been one of its vice-presidents since 1884. In 1883 the Emperor-King Francis Joseph conferred upon him the Order of the Iron Crown. Dr. Duka was the author of a life of the Hungarian, Alexander Csoma de Körös, the earliest student of the Tibetan language, and he promoted in this country the movement which led to the erection of a memorial at Budapest to Semelweiss, the pioneer of antiseptic midwifery.

DR. TURNBULL OF KELSO.

The death is announced of Dr. George Hogarth Turnbull, one of the oldest medical practitioners on the Border. The deceased had for many years practised in Kelso, and was held in high esteem throughout the district. He died in harness, being at the onset of his last illness in actual attendance at the house of one of his patients. There he was suddenly struck down by an apoplectic seizure on May 9th, and died on the following morning. He was an ardent Volunteer, and up to quite recently was in command of the Medical Corps connected with the Scottish Border Brigade.

REVIEWS OF BOOKS.

PRACTICAL MEAT AND FOOD INSPECTION. (a)

Meat and food inspection is a most important factor in preventive medicine, and although the subject is receiving more prominence than formerly, it is eminently desirable that the student of public health should favour the matter with still more attention. Dr. Robertson's book is to be highly commended for his treatment of the matter in a way calculated to render the student's studies of most service to him. The sanitary aspect of sound and unsound food is not merely the approval of condemnation of food on the absence or presence of pathological, bacteriological, and chemical evidences. It goes far deeper than this and embraces the prevention of such abnormal conditions, by a suitable supervision over the conditions and methods of production. Hence the undoubted wisdom of devoting so much space to a consideration of what constitutes suitable and unsuitable cowsheds, piggeries, stables, slaughter-houses, to methods of slaughter, storage, carriage, and preservation of food. For this portion of the work we have nothing but praise, as unnecessary verbiage is non-existent, and the author possesses a remarkable grasp of his subject that allows him to speak with considerable authority. The specific appearances of meat in its various conditions, and the significance of the same are treated in a way that leaves little to be desired, and the only complaint we have with the book is that we should have liked more of it, as in order to give proper consideration to meat and milk, other articles of food have been neglected or ignored. To a certain extent this is remedied by the admirable collection of footnotes to the second part (The Laws relating to Food Inspection, by R. H. Miller, S.S.C., Public Prosecutor for Leith Local Authority), which will be found invaluable to all interested in the subject. Incidentally these footnotes allow a view of the scandalous ways in which the public may be defrauded without the law as it at present exists being able to afford them redress. Some of the cases cited are rulings that, however, are not invariably followed when justices follow the spirit as well as the letter of the law. The law relating to the subject of the various forms of food presents some curious issues, and this collection of legal notes affords a considerable insight into the difficulties of those who have to decide on the rights and wrongs of the matter.

DELAFIELD'S PATHOLOGY. (b)

In this, the eighth, edition of Dr. Delafield's well-known Pathology, the distinguished author has been replaced entirely by his junior colleague, Professor Mitchell Prudden, who now takes sole responsibility for all the statements made and views expressed. A good deal of revision and re-writing, of course, has been necessary in dealing with such a rapidly-widening subject as pathology, and Professor Mitchell Prudden has had the advantage of much help, which he duly acknowledges, from his colleagues, especially from Professor Wood, who has written the section on the Nervous System. The result is the production of a most admirable text-book, completely adapted to the requirements of students, and easily handled by a practitioner on the look-out for a reference. The book is, we hope, so well known that we look to this edition as to only a phase in its career of usefulness, for we imagine that at present it is, within the limits of its scope and intention, as well-written, well-composed, and well-formed a text-book as there is in the field. The chapters and descriptions are at times somewhat unsatisfying; but consideration of the enormous mass of facts to be dealt with reminds us that it is not the author's fault that he does not say more, but the demands of stern necessity. The illustrations are worth more than a passing word; they are uniformly successful in portraying the points at issue, and in some instances, notably, perhaps, in Fig. 312—Chronic Endocarditis with Calcification of the Thickened Valves; fig. 427—Miliary Tuberculosis of the Omentum; fig. 432—Fat Necrosis in the Mesentery; and fig. 563—Carcinoma of the Mamma—Fibrous Type—Scirrhus—we might be looking into the specimen-jar itself. Colour is used in some of the plates very effectively, and the full-page coloured illustrations of changes and the morphology of the blood, the lesions of ganglion cells, stained by Nissl's method, and so on, give all that the heart could desire. Bacteriology is only dealt with incidentally in this work, but as a guide to morbid anatomy and microscopical pathology it is a signal success.

AIDS TO OPHTHALMOLOGY. (a)

That this book should have reached a fourth edition seems a sufficient test of its utility. Originally, the *brochure* was written by Mr. Jonathan Hutchinson, but that gentleman no longer practices ophthalmic surgery as a speciality, and the new edition was given into the hands of Mr. Bishop Harman, F.R.C.S., than whom no one is more competent for the work. The book contains a clear and concise account of the chief diseases of the eye, together with a very good description of elementary refracton. This "Aids to Ophthalmology" should prove most serviceable both for students preparing for examination and to those engaged in general practice. Although the lapse of time has necessitated rewriting most of the material to bring it up to present-day knowledge, Mr. Hutchinson's practical methods and attractive style have, fortunately, been preserved by the new editor, whom we congratulate on the result of his congenial taste. The illustrations, 70 in number, are most excellent.

DISEASES OF OCCUPATION. (b)

It is always a pleasure to read a book written by a man who knows his subject, and Professor Oliver is generally acknowledged to be the highest authority in the country on occupation diseases. That alone would make the work before us a highly valuable one, but its worth is greatly enhanced by the author's literary skill. He writes with ease and lucidity, so that the reader follows him with a comfortable feeling through the mazes of a very intricate subject, or rather series of subjects. To explain the processes of a number of trades is no easy matter when it is not wished to go into technicalities, and we ascribe to the author the mastery of the great literary art of concealing art, and of presenting in a few bold strokes just what the reader wishes to know about a trade for the purpose of understanding its dangers, without wearying him with superfluous incidental detail. It is the fruit of this faculty which gives the volume its claim to be called "popular"—for it is one of Messrs. Methuen's "New Library of Medicine" designed for reading by the intelligent public—but from the very character of the subject it cannot be expected to supplant or compete with those books which present systems of "health" culture or prescribe dietaries for the neurasthenic or the hypochondriac. In a word, Professor Oliver's work is popular in the best sense—the intelligent layman, if he is thinking of others and not of himself, and is not averse to applying his mind to the subject, may find reading that is pleasant, profitable, and extremely important. To factory surgeons, medical officers of health, and medical practitioners generally, we can not only cordially recommend its perusal, but we unhesitatingly pronounce it the best manual, written singlehanded, that we know. One of its most important features is that the author does not by any means confine himself to British experience, but he has furnished himself with comparative information from all civilised countries, and he is thus enabled not only to lend further and fuller illustration to his points, but to reinforce and drive home his conclusions. The subject of "Occupation Diseases" is one that is being more widely studied every year, and under the Workmen's Compensation Act, 1906, it has, for the first time, assumed a definite legal importance. The matter cannot long rest where it is, for it is quite illogical that an employer should pay for lead-poisoning and anthrax contracted in his business, and be relieved of any obligation with regard to tuberculosis or anæmia caused by occupation conditions. It is true that medical science cannot yet asseverate positively that many diseases, such as tuberculosis, are solely the outcome of factory conditions, but the day may come when it will, and doubtless the employer's liability will be proportionately increased. But in the meantime, no one caring for the public health can afford to neglect what is already known, and he can derive such information with great facility and advantage from Professor Oliver's book.

(a) "Practical Meat and Food Inspection." By William Robertson, M.D.Glasg., D.P.H., Medical Officer of Health, Leith, formerly Medical Officer of Health, Perth and Paisley. Pp. x, and 372, with 40 illustrations. London: Bailliere, Tindall and Cox. 1908. Price 10s. 6d. net.

(b) "A Text-Book of Pathology." By Francis Delafield, M.D., LL.D., Emeritus Professor of Medicine, College of Physicians and Surgeons, Columbia University; and T. Mitchell Prudden, M.D., LL.D., Professor of Pathology, Director of the Department of Pathology, College of Physicians and Surgeons, Columbia University. Eighth edition, 13 full page plates, 650 illustrations in black and colour. London: Bailliere, Tindall and Cox. 1908. Price 25s. net.

THE PYONEX. (a)

In the study of the history of medicine one cannot fail to be struck with the fascination which an universal remedy for disease has had at all times on the minds of some members of that profession. For ages large numbers of the learned men of the world devoted their lives to the search for the elixir of life, which was to banish all disease and confer on its fortunate possessors perpetual youth and health. Later, in spite of the growth of science, we continually meet with those who assert that they have found some remedy which will cure, not only many, but all diseases. If this assertion is made with sufficient frequency and loudness it is sure to gain a hearing, and if the personality of the author is sufficiently striking he is sure to gain a large following of believers. Paracelsus, Mesmer and St. John Long are examples of persons who have acquired fame and wealth by such means, and the income made in our own day by vendors of the various quack medicines is evidence that in this respect the public has not changed much from what it was in the days of Mesmer and Long. The author of the work before us does not claim an absolutely universal remedy, but he does claim that by the treatment which he prescribes most disease can be cured. Mr. Rule, however, differs from those who have gone before him in one important respect, for he claims these advantages for the method and not for himself, and he fully describes this method so that any one may make use of it.

What, then, is this method, and on what considerations is it based? There are three fundamental principles on which the treatment is based. "(1) That nearly all disease is caused by some abnormal, extraneous, or foreign element in the affected tissues or in the blood. (2) That congestion, pain, swelling, discolouration, inflammation, disorganisation and suppuration are only symptoms and sequences that are produced by the said foreign element. (3) That if the said foreign element be totally removed, the said symptoms disappear," Such propositions appear plausible enough, but they are quite incapable of bearing the superstructure which our author has raised on them. This superstructure is held together by the most curious smattering of pathology that it has ever been our misfortune to come across. The "extraneous or foreign element," whether it be animal, vegetable, or chemical poison, often causes in the human body the formation of pus, and from this our author is "led to the conclusion that diffuse purulent infiltration of the tissues is the cause of the majority of the more serious ailments," and if this pus is removed there will be a perfect restoration of the integrity of the tissues and of the health of the individual. The "pyonex" is the instrument by which this removal is effected. The instrument resembles a magnified Rose's vaccinator with 33 needles inserted into a metal boss, which is movable in the containing case. This boss is attached to a spiral spring, and when this spring is pulled out about half an inch and suddenly let go "a slight blow is thereby caused on the return stroke, when the needles come in contact with the epidermis. This blow is sufficient to produce minute pores in the epidermis, but the needles are not allowed to penetrate deep enough either to cause pain or to permit of very minute points of blood appearing on the surface." Five or six such applications are made to the skin at distances of about one and a-half or two inches from each other, and then over this area the pyonex oil is applied with a stiff brush. This oil consists of sweet almond oil, "lytta" and "euphorbium," but "it is open to any practitioner to compound the oil of such ingredients as may commend themselves to his judgment." This oil first acts as a stimulus to "the peripheræ of the nerves that are thus exposed," and then "enters the capillaries and becomes distributed to the surrounding parts." This oil sets free the morbid poisons in the tissues, which are then "brought together and expelled through the same artificial pores which served as an entrance for the oil." The occurrence of pustules at the site of the pyonex application is evidence of disease, and from the nature and quantity of this pus the severity of the disease is estimated.

All sorts of diseases are treated with success, and the pathological anatomy of some of them, as described by our author, is most remarkable. In cases of gout the pus shows on microscopic examination well-developed colonies of the gout bacillus, but this method of examination is not necessary, for "they come out in a dry condition and may be removed from the body between the thumb and finger." In a case of rheumatoid arthritis an examination of the blood was made under the microscope, "and showed adherent and matted corpuscles, and about double the right number of leucocytes; litmus paper showing the whole to be loaded with acidity." Of another case we read, "Very little pus was expelled, but my attention was drawn to an immense number of minute organisms which were expelled from the chest, back and other parts. The patient stated that for some years past they had been coming out, and that it was awful to have such things in her body. She also wished for information as to what they were. They could be picked off from the skin with the thumb and finger, and their expulsion was accompanied by intense itching. Several of these were collected and placed in a small phial; and on submitting them to an examination under the microscope I discovered they were all well-developed colonies of a bacillus, which was identical in appearance to the "anthrax bacillus." In another case a lady with severe dilatation of the heart was treated. In her case "the heart is so distended that it pushes the left arm away from the side," yet after two applications she is quite cured.

We have, however, said enough to indicate the nature of the book and the kind of teaching that it contains, it may at some future date be looked on as a medical curiosity, but we doubt if it will in any way advance our knowledge.

DISEASES OF THE SKIN. (a)

Dr. Henry W. Stelwagon's "Diseases of the Skin" is a fine example of what the systematic treatise on a special subject should be. It is full, exact, well-thought-out, well-arranged, and well-illustrated. We may also say that while the classification of skin diseases remains in its present chaotic condition, we support the author in the easy and natural scheme which he has adopted, and which can be made to cover all diseases except a few of uncertain pathology. Not only, however, is the scheme of the work commendable, but its execution leaves little to be desired. The descriptions of most of the conditions are clear and business-like, and a wealth of literary references is added in the case of rare and curious diseases. Although pathology and diagnosis are by no means neglected, indeed, they are very fully considered, the point that strikes us most is the amount of space given to treatment and the many suggestive plans therein set forth. In a word this is a practical book, and its value as such is enormously increased by the illustrations. Of these we must say a word. The coloured ones are quite up to the standard we have grown accustomed to expect from Messrs. W. B. Saunders, which we consider very high praise indeed, and the half-tones, to our mind, are even better than the coloured plates. What, for instance, could be better than the illustrations of variola, notably plate xvii., or that of a case of eczema seborrhœicum on plate x.? They are quite up to the best standard of half-tone work, and they give at a glance a natural, vivid, clinical picture. We do not quite agree with the author in all his views, that would, perhaps, be impossible to expect; but his teaching is thoroughly sound and luminous, and we wish his fifth edition even greater success than the preceding four.

(a) "Diseases of the Skin." By Henry W. Stelwagon, M.D., Ph.D., Professor of Dermatology in the Jefferson Medical College, Philadelphia. Fifth edition, revised. Philadelphia and London: W. B. Saunders' Company, 1907.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (*a*)

THIS volume contains fifteen medical and five surgical papers, as well as the usual statistical tables of the patients under treatment in the hospital during the year 1906, compiled by the medical and surgical registrars. As usual in St. Bartholomew's Hospital reports, the papers are all interesting and well repay perusal, and we regret that the space at our disposal does not permit of a detailed reference to each. We should like, however, to draw particular attention to the very interesting paper by Dr. A. E. Garrod, on "The Initial Stage of Myositis Ossificans Progressiva." In this paper is recorded the history of a child who at five months of age presented some lumps on the head. These completely disappeared in the course of a few months, but later fresh swellings developed in the back. Eventually all the swellings seemed to disappear, and the child was taken by its parents to South Africa. In June of last year Dr. Garrod obtained the following report from Dr. Gurney, under whose care the child was in Cape Colony:—"I see the boy from time to time; unfortunately the disease seems to be progressing. The biceps of the right arm is contracted and feels stony hard; the elbow-joint is fixed and also the right shoulder to a certain extent. There is also a nodulated lump about the size of a tangerine orange over the lower part of the infraspinatus which has the consistence of bone. There are several other lumps forming, the most noticeable of which are on the left side of the spine, about three inches distant from it, and three or four inches below the angle of the scapula. The child's health seems to be perfect."

We regret very much that some more information is not given in the reports concerning the statistics of anæsthetics. Two deaths only are recorded in 7,136 administrations, but we are not afforded any information as regards these two fatal cases.

MEDICAL NEWS IN BRIEF

Royal College of Surgeons of England.—Ordinary Council, 14th May, 1908.

AT a meeting of the Council of the College on Thursday last, May 14th, it was reported that 169 candidates were admitted to examination in Surgery at the Pass or Final Examination for the Diploma of Member, concluded on the 16th April, 1908, and that of these candidates the following 101 passed and received the M.R.C.S. Diploma, the remaining 68 were referred to their professional studies:—

Alex. R. Alguire, Kekobad C. Anklesaria, Charles J. Aveling, Ardeshir P. Bacha, Henry Bardsley, Dinshá D. Báriá, James W. Bennett, Charles T. V. Benson, Robert N. W. Biddulph, Bernard R. Billings, George S. Candy, Geoffrey D. H. Carpenter, George F. Carr, William J. Carr, Edmund V. Connellan, Ernest N. Cook, Cyril D. H. Corbett, Alfred E. Cullen, D. I. Dakeyne, Archibald Davidson, Thomas B. Davies, Edward J. Dermott, Harold B. Ellison, Robert C. T. Evans, Alfred W. Ewing, Edwin G. Fearnsides, Gaetano J. Fernandes, Harold H. B. Follit, Henry G. Frean, Harold S. Furness, Alexander H. Gifford, William C. Gilday, Henry L. Grabham, Harry M. Grey, Kenneth G. Haig, William R. Harris, Alfred E. W. Hird, Frederick W. Hobbs, F. G. Holder-Williams, Edward H. V. Hodge, Charles E. Howden, Howell T. Howells, Ernest E. Isaac, George L. H. Johnston, John M. Johnston, Ratanshaw B. Khambata, Framroze J. Kolaporewalla, Alfred V. Ledger, Walter E. Lloyd, Arthur A. Lynch, Charles K. McKerrow, Oswald W. McSheehy, Edward K. Martin, James B. Mennell, Alfred Miles, John G. Morgan, Reginald Mugliston, Berthold Muir, Bhola Nauth, Mark A. Nicholson, Rupert H. Nolan, Arthur C. Oliver, Max Onslow-Ford, Albert H. Owen, William N. A. Paley, Norman C. Patrick, Thomas G. Percival. William J. Petty, George H. Pooley, Dan A. Powell, John W. Power, Kenneth Pretty, Sharles E. Price, Robert C. Priest, Kenneth D. Pringle, Ernest A. Pywell, William E. Roberts, Hubert A. H. Robson, Harry A. Sanford, Chales F. O. Sankey, James E. Sawdon, Frank S. Scott, Clovis L. Seccombe, Francis R. Smyth, Robert Svensson, Arthur J. Symes, John Thompson, Percy S. Tomlinson, Geoffrey Viner, Basil Wallis, Paul I. Watkin, Charles H. S. Webb, Thomas A. Weston, Charles F. O. White, Samuel E. Whitnall, Harold F. Whittall, William Wijegoonewardena, Charles M. Wilson, Graham L. J. Wilson, Henry A. F. Wilson, Charles S. E. Wright.

The Irish Universities Bill.

MR. BIRRELL'S Bill for the establishment of new Universities in Dublin and Belfast respectively, passed its second reading by a large majority on the 11th inst. It has now been referred to a Standing Committee for the next stage. During the past weeks many public meetings have been held at which the Bill has been the chief subject of discussion. The Convocation of the Royal University of Ireland adopted a resolution stating that it was desirable that the exclusion of extern students should not be enforced for a period of ten years instead of after five years as stated in the Bill. Convocation also requested that the occasion of the transferring of graduates of the Royal University to the new University should not be made an occasion for the promiscuous granting of honorary degrees. The Senate of the Royal University have unanimously agreed that the sums allotted to the new Universities and their constituent colleges for buildings and maintenance are entirely inadequate.

Proposed Memorial to the Late Dr. Conolly Norman.

IT is felt that some steps should be taken to perpetuate the memory of the late beloved and honoured Medical Superintendent of the Richmond Asylum, of whom it may be truly said that his works live after him. By his exertions the largest asylum in Ireland was transformed from a place of misery to a hospital where the afflicted might regain mental health, or, if that was impossible, might have a home where they might receive care and kind treatment to the end of their days. He was at once the servant and the protector of the afflicted poor, and his life was devoted to those from whom most men shrink.

Dr. Conolly Norman was also a man who was most accomplished in his scientific work, and added materially to the literature of mental disease. It is desired, therefore, that any memorial that may be erected should be a tribute not solely from his medical colleagues, but from all classes. With this object a preliminary meeting was held at the Royal College of Surgeons on the 7th ult., when a General Committee was constituted. At this and subsequent meetings the following conclusions as to the form of memorial were arrived at, viz.:—That if sufficient money is collected it should be devoted to two objects: First, to the formation of a "Conolly Norman After-Care Association," to benefit poor and friendless patients on their discharge from the Richmond Asylum. Such a charity is sorely needed, as patients sometimes leave the asylum with no home to which to go or friends to assist them. These poor people might be helped to

---

(*a*) "St. Bartholomew's Hospital Reports. Vol. XLIII." Edited by H. Morley Fletcher, M.D., and W. McAdam Eccles, M.S., F.R.C.S. London: Smith, Elder and Co. 8vo. Pp. xxvii, 252, viii, 187. 1908.

find work—often a matter of great difficulty in such circumstances—assisted with gifts of clothing, and maintained while they seek for employment. Such an Association would carry on his work and perpetuate his memory in the way most consistent with his life. Secondly, it is hoped that Dr. Conolly Norman's portrait may be painted and hung in the Royal College of Physicians, of which he was the Vice-President. Subscriptions will be received by the Honorary Treasurers—W. R. Dawson, Esq., M.D., Farnham House, Finglas, Dublin, and J. R. O'Connell, Esq., LL.D., 34, Kildare Street, Dublin.

"Medical Specialist" Sentenced.

BERTRAM MORTIMER, 50, described in the calendar as a "medical specialist," was found guilty at the Clerkenwell Sessions, on May 14th, of having stolen a Gladstone bag, containing property value £12, from the cloak-room at the Victoria Station of the London, Brighton and South Coast Railway.

Mortimer's son, who gave his name and description as "Hubert Sylvester, 23, physician," was acquitted of having been concerned in the theft, and was released.

The bag was issued by mistake to Mortimer, and he retained it.

Detective-Sergeant Barrett said the prisoner, Mortimer, had had a somewhat extraordinary history. For years up to 1881 he was a captain in the Salvation Army at Bath, but he was then allowed to resign through misconduct. For some time afterwards he went to sea as a sailor on board trading ships. In 1882 he was twice fined for assault, and in 1883 was sent to prison for seven days, in 1885 for one month, and in 1892 he was fined £5 for drunkenness and assaults. On November 26th, 1897, at Bristol Assizes, he was sentenced to fifteen months' hard labour for conspiring to procure a girl for an unlawful purpose, and in 1899, at the Wells Assizes, he received one year's imprisonment for bigamy. Since his release he had been travelling all over the country, calling himself "Professor Sylvester, medical specialist." His real name was Powell, but he had used various names —Browne, Fowler, Fox, Lynton, etc. He imposed on people by representing that he had discovered a speciality—a wonderful gold-dust cure. All that the "cure" consisted of apparently was to receive the fees, no remedy being supplied. For years past the Medical Defence Union had had numerous inquiries about him from all over the country, and they wished this fact brought to the notice of the Court. Witness read the following circular, sent broadcast by Mortimer:—

"A revelation to sufferers. To heal the sick. To cure the diseased. To restore the suffering to health. The great American doctor, Professor Sylvester (M.D., D.Sc., Boston, Mass, U.S.A.). This eminent American expert has opened a practice for the benefit of the sick and the suffering. Countless numbers have been saved from early graves, and hundreds are rejoicing who have been told their cases were hopeless. See this marvellous expert and be convinced. No quackery, no patent medicines. This eminently qualified medical specialist is at your service—absolutely free."

Mr. Robert Wallace, in ordering Mortimer fifteen months' imprisonment in the second division, said he would assume that that sentence would put an end to the other proceedings at Swansea.

Royal College of Surgeons in Ireland—Election of Examiners

AT a meeting of the President, Vice-President, and Council, held on Tuesday, May 5th, the following Examiners were elected for the ensuing year:—

COURT "A." — Anatomy. — Alexander Fraser, F.R.C.S.; Bertram C. A. Windle, B.S. Surgery.—Charles A. K. Ball, F.R.C.S.; Alexander Blayney, F.R.C.S.; E. Conway-Dwyer, F.R.C.S.; Robert J. Harvey, F.R.C.S. Physiology and Histology.—Denis J. Coffey, B.S.; E. L'Estrange Ledwich, L.R.C.S. Pathology and Bacteriology. — Arthur H. White, L.R.C.S. Midwifery and Gynæcology.—Frederic W. Kidd, L.R.C.S. Biology.—John J. Burgess, F.R.C.S. Ophthalmology.—Arthur H. Benson, F.R.C.S.; Herbert H. B. Cunningham, F.R.C.S. Sanitary Law and Vital Statistics.—Edward F. Stephenson, F.R.C.S., D.P.H. Engineering and Architecture.—James H. Fergusson, F.R.C.S., D.P.H. Languages.—Latham J. Woodroffe, M.A. Mathematics, Physics, Dictation, and English.—John W. Tristram, M.A.

COURT "B."—Anatomy.—Patrick J. Fagan, F.R.C.S.; Alexander Fraser, F.R.C.S. Surgery.—Charles A. K. Ball, F.R.C.S.; Alexander Blayney, F.R.C.S.; F. Conway-Dwyer, F.R.C.S.; Leveson G. Gunn, F.R.C.S. Physiology and Histology.—Denis J. Coffey, B.S.; E. L'Estrange Ledwich, L.R.C.S. Pathology and Bacteriology.—Robert J. Rowlette, M.D.; Arthur H. White, L.R.C.S. Midwifery and Gynæcology.—Frederic W. Kidd, L.R.C.S. Chemistry and Physics.—Edwin Lapper, L.R.C.S.; Robert J. Montgomery, F.R.C.S. Dental Surgery and Pathology.—George M. P. Murray, F.R.C.S.; William G. Story, L D.S. Mechanical Dentistry.—Daniel L. Rogers, L.D.S.; Edward Sheridan, L.D.S.

Society for Relief of Widows and Orphans of Medical Men.

THE annual general meeting of the above Society was held on Thursday last, May 14th, Dr. G. Fielding Blandford in the chair. Seven directors were elected to fill the vacancies in the Court. The report for 1907 stated that during the year 11 new members were elected, and 10 died. The invested funds now amount to £99,260, from which is derived in interest the sum of £3,118 2s. 5d., whilst £433 0s. 3d. was received in subscriptions and donations. Amongst the annuitants—namely, 49 widows and 17 orphans, the sum of £3,151 10s. was distributed. Forty-three widows received £50 each, four £40, one £30, and one £25, with £10 each extra at Christmas, and each orphan £12 and £3 extra at Christmas. During the year two widows in receipt of grants died. One, whose husband had paid in subscriptions £26 3s., received £490; the other, whose husband had paid in annual subscriptions £27 6s., received £2,824; she had been in receipt of grants since 1866. One of the widows still in receipt of grants has been on the books since 1854, and has already received over £2,060. The annual subscription is 2 guineas to residents within the radius of 20 miles from Charing Cross; every member who has paid this sum for 25 years becomes a member for life. Life membership may also be obtained by the payment of one sum, varying with the age of the applicant. Further particulars and application forms may be obtained from the Secretary at the offices of the Society, 11, Chandos Street, Cavendish Square, London.

Royal University of Ireland.

AT a meeting of the University, held on May 14th, the following degrees were conferred:—

M.D.—James G. Campbell, William H. Davis, Joseph P. Dee, Denis J. Keane, Thomas D. Luke, William Rice, and John Thompson. M.B., B.Ch., B.A.O.—Robert G. Kevin, Arthur H. Joy, Joseph G. Johnston, Marshall F. Huston, Thomas J. Hollins, B.A., Donal Barry, Arthur R. Boyd, Thomas A. Carson, James K. P. Clarke, Thomas P. Linehan, George H. Martin, Thomas Arnold, Raphael N. Berman, William Bradbury, Thomas G. Buchanan, Robert J. Clarke, Mary Cowhy, B.A., Edmund H. Flanigan, William S. Graham, Hugh J. Grant, Patrick J. Grogan, Richard G. C. M. Kinkead, Robert J. Ledlie, Solomon Levy, John C. Macaulay, Joseph M. Causland, B.A., Michael McNiff, James F. Neary, John F. Neary, John F. O'Brien, Michael Waldron, George P. White, Michael White.

The following Exhibitions have been awarded:—

The Second Examination in Medicine.—Exhibitions. —First Class, £25.—Henry L. Barniville. Second Class, £15.—William K. Calwell.

The Third Examination in Medicine.—Exhibitions. —First Class, £30.—William W. D. Thomson, B.A. Second Class, £20.—Walter Mooney, B.A.

The M.B., B.Ch., B.A.O. Degrees Examination.— Exhibitions, £21 each.—In Medicine Group, Robert G. Kevin. In Surgery Group, Arthur H. Joy. In Midwifery Group, Joseph G. Johnston.

Fire at Gordon College, Khartoum.

AN alarming fire broke out in the Wellcome Research Laboratories, Gordon Memorial College, Khartoum, on May 11th. Before it was got under control considerable damage was done.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Purpura Hæmorrhagica with Cerebral Hæmorrhage.—Carruthers reports a case of the above (Clin. Section. *Proc. Royal Soc. Med.*, Vol. I., No. 6, p. 120). The patient was a woman, æt. 59, who first suffered from several cutaneous ecchymoses, which continued to spread, in spite of treatment. Ten days after the patient was first seen there was some hæmorrhage from the nasal and intestinal mucous membranes, and shortly afterwards symptoms of cerebral hæmorrhage showed themselves, there being, in addition to coma, jerky, spasmodic movements of the right side of the body. These symptoms suggested that the hæmorrhage was a cortical one. Death occurred suddenly in coma, apparently from a further medullary lesion. M.

Acute Suffocative Catarrh of Laennec and Allied Conditions.—West describes a case of Laennec's suffocative catarrh, and discusses the conditions with which it may be confounded (*Proc. Royal Soc. of Med.* Medical Section. Vol. I. No. 5, p. 161). His patient was a man, æt. 23, admitted to hospital suffering from extreme dyspnœa and cyanosis. He had been in perfect health till 36 hours previously, when he felt some tightness and contraction in his chest. On examination some sibilant rhonchi were audible, but otherwise the chest was normal. The temperature was 100° F., respiration 36, and pulse 120. Under treatment the condition quickly improved, crepitation appeared in the chest, and there was a little mucoid expectoration. This case West regards as a typical example of what Laennec described. He enumerates, under three headings, the conditions which may be mistaken for it, as follows:—(1) Acute suffocative pulmonary œdema. This he regards as due to sudden failure of the heart, and divides the cases into those with and those without antecedent cardiac disease. The characteristic symptoms are sudden onset of dyspnœa and cyanosis, accompanied by profuse expectoration of blood-stained watery fluid. (2) Certain acute inflammatory conditions. This includes some cases of severe capillary bronchitis, secondary broncho-pneumonia, and more especially acute primary broncho-pneumonia. (3) Collateral fluxion and respiratory failure. Under this heading is included conditions such as acute bronchitis occurring on one side in association with a pleural effusion, or consolidated pulmonary area on the other. These conditions will not be mistaken for suffocative catarrh, but are allied to it physiologically. M.

Erepsin in the Intestinal Canal of Fœtuses.—Langstein and Soldin have examined the intestine of a new-born calf for the presence of erepsin, and also the intestinal juices of human fœtuses from 4½ months to 7 months (*Jahrt. f. Kinderheilk*, Bd. 691, S. 9). They found that erepsin was present in the calf, and also in the intestines of viable fœtuses, but could not detect the presence of any in non-viable fœtuses. M.

Leukæmia in Dogs.—Outakakon has investigated some cases of leukæmia occurring in dogs (*Virchow's Archiv.*, Bd. 190, H. 2). He states that the lymphatic variety is commoner than the myelogenic. The post-mortem examinations showed general pallor of all the organs, with enlargement of liver and spleen, and a change of the yellow marrow to a greyish red colour. Microscopically there was diffuse cellular hyperplasia of marrow and spleen, and some cellular infiltration of other organs. There was a great increase of white cells in the blood, principally of a round mononuclear variety. No enlargement of the lymph glands was, however, found. M.

Hæmatemesis following Extirpation of the Spleen.—Leiblein has observed in Wolfler's clinic at Prague two cases of profuse hæmatemesis following excision of the spleen (*Centralbl. für Clin. Med. Wissenschaft.*, January 25th, 1908). With the exception of one other case recorded by Laing, these are apparently the only recorded instances of this extremely rare complication. The writer believes that the cause of the bleeding must be that in tying the pedicle of the spleen the vasa brevia of the stomach are included in the ligature. This can readily occur, since the vasa brevia, according to French writers, frequently arise, not from the main trunk of the splenic artery, but from one of the branches into which it divides almost immediately before it sinks into the substance of the spleen. Another possible cause is that during the operation one or other of the larger gastric vessels may be slightly injured, and may later on rupture and cause the bleeding. M.

Experimental Observations on Secretin.—Sweet and Pemberton (*Archives of Internal Medicine*, March, 1908) report on their work on secretin, which was done with especial reference to diabetes and malnutrition. The authors come to the following conclusions from their work:—(1) There would seem to be some factor which makes the preparation of secretin from human intestines more difficult than from the intestines of some animals. (2) This factor may depend on the relatively great abundance of membrane in these animals, and consequently greater amount of pro-secretin. (3) The abundance of mucosa may be, in fact, a provision of Nature in order that the strongly acid chyme of some animals may meet with a quantity of pancreatic juice sufficient to neutralise it and effect digestion. (4) Active preparations of secretin can be made with hydrochloric acid of widely varying strengths, and activity *in vivo* is apparently not dependent on the peculiar acidity of the chyme in any particular animal. (5) Dieting and fasting seem to have no appreciable effect on the activity of the extract. (6) The evidence so far adduced that secretin is absent in some varieties of diabetes does not seem conclusive. (7) The specific absence or deficiency of secretin in marasmus seems to remain as yet unproven. D.

Statistics of Serum Treatment of Scarlet Fever.—Pulawski (*Deut. Med. Woch.*, February, 1908) has treated 103 cases of scarlet fever since 1904 with a serum prepared by injecting a horse with streptococcus from a severe scarlet fever case. He used very small doses, and only one case was injected three times. His results were roughly three times as good as in those treated by the ordinary measures. There were no bad results from the serum. D.

The Oatmeal Diet in the Treatment of Diabetes Mellitus.—Herrick (*Journal Amer. Assoc.*, March, 1908) in the main confirms Von Noorden's claims for the oatmeal diet. In the milder types of diabetes there were no ill-effects, but the benefits seemed slight. In the cases of moderate severity it seems of especial help in establishing tolerance for carbohydrates, and in warding off impending coma. In Herrick's cases he found it to exert a very favourable influence in the diabetes of children, if employed early. D

Hysteria in Children.—Price (*Archives of Pediatrics*, New York, February, 1908) concludes that girls are more frequently, boys more severely affected with hysteria. Predisposing ætiologic factors are heredity, faulty environment, and education, any condition lowering the vitality or causing continuous irritation of the nerve centres. The symptoms are essentially the same as in the adult, but slightly modified. Suggestion in one form or another he regards as of paramount importance in the removal of symptoms, but we must never lose sight of the probability of an underlying neuropathy. Hypnotism he mentions only to condemn, holding that the experiments of Charcot, Babinski, Dercum and others have shown it to be only artificially induced hysteria. He presents four cases of the following less common forms:—(1) Hysterical tremor. (2) Hysterical joint. (3) Psychic type. (4) Hysterical dyspnœa. D.

Relation of the Parathyroid to Calcium Metabolism and the Nature of Tetany.—McCullum and Voegtlin (*Johns Hopkins Hospital Bulletin*, March, 1908) found that all the violent symptoms produced by parathyroidectomy, muscular twitching, fibrillary temors, increased rapidity of the heart, etc., may be almost instantly cured by intravenous injection of a solution of calcium salt. The acetate or lactate in a 5 per cent. solution was usually employed. Subcutaneous injection or the introduction by mouth seemed as effective, but acted more slowly. The tetany may reappear in 24 hours, but disappears immediately upon the renewed administration of calcium. Magnesium salts seem to have a somewhat similar effect, but the results are obscured by the toxic action of the salt. Potassium salts intensify the symptoms. Incomplete studies of the excreta and blood of the parathyroidectomised animals tend to show an increased output of calcium in the excreta and a diminished calcium content in the blood. The writers construct the working hypothesis that the parathyroids control the calcium metabolism of the body. D.

Typhoid Carriers.—Davies and Hall (*Bristol Medico-Chirurg. Journ.*, March, 1908) discuss the very interesting problem of the connection between typhoid carriers and sporadic outbreaks of typhoid fever. The death-rate from typhoid fever has steadily declined, for in the decade 1871-1880 the death-rate per million living was 322, while from 1891 to 1900 it was only 174, although during this period the case mortality has remained fairly constant at about 17 per cent. There seems to be no doubt that the decline in the prevalence of the fever is due to the general improvement in the drainage and water supply, but there still remain a residuum of cases which do not seem capable of explanation by any defects in sanitation. It seems more than probable that many of these cases may be explained by personal infection through people who are chronic typhoid carriers. There are on record several cases where this connection has been demonstrated, among which may be mentioned the Inebriates Home near Bristol, recorded in the *British Medical Journal*, January, 1908, by A. and J. C. G. Ledingham. It is stated that 4 per cent. of typhoid convalescents become carriers, and the condition has been known to persist for as long as ten years. It seems quite possible that it may be necessary to insist that typhoid convalescents must be proved to have their excreta free from typhoid bacilli before they are re-admitted to society, just as diphtheritic patients must be shown to be free from the diphtheria bacilli. K.

Notching of the Lower Incisors in Congenital Syphilis.—Wallis (*Brit. Journ. of Children's Diseases*, March, 1908) records a case in which this condition was well marked in a child, æt. 12, with other signs of congenital syphilis. He believes that the condition is not at all so uncommon as is thought. He has himself three such cases under his care, and records this one in hopes that further observations may be made by others with a view to finding out the percentage of cases of congenital syphilis in which the condition is shown. K.

Use of Chrysarobin in Psoriasis.—Norman Walker (*The Scottish Med. and Surg. Journ.*, April, 1908) publishes an interesting paper on this subject, illustrated by two excellent coloured plates. If good results are to be obtained from this treatment it is necessary that the patient should give himself up to the treatment, and if he expects to be cured without interfering with his ordinary avocations some other method than the chrysarobin one ought to be chosen. Walker believes that continuous application is the most important factor in the treatment, and the best preparation of the drug is the simple ointment of half a drachm of chrysarobin to the ounce of vaseline. The method which he adopts is as follows: The patient is given a bath and the scales removed with a nail-brush, and this is followed by a soft soap dressing which may remain on for twenty-four hours. This dressing is followed by another bath to remove any excess of alkali before the chrysarobin treatment begins. The exact distribution of the eruption is then noted, and the patient rubbed vigorously all over with a five per cent. chrysarobin ointment, after which dressings spread with the same ointment are carefully applied to every part of the surface from the neck downwards. In about seven days a well marked erythema of the healthy skin areas is developed, the psoriasis spots still remaining pale. It is of the greatest importance that the treatment should be continued till the affected spots show a distinct erythema, and this is the meaning of Pautrier's phrase, "Pas d'érythème, pas de guérison." The affected areas will be found erythematous in from about eight to eleven days after the commencement of the treatment. After this one or two warm baths are taken, and the patient will be found free from disease. It is important to make a thorough investigation of the patient once or twice during the treatment to see that there are no lagging spots, if such be found they should be treated by an ointment in which other drugs, such as salicylic acid, are brought to the aid of the chrysarobin. K.

Lupus Erythematosus associated with Nephritis.—MacLeod (*The Brit. Journ. Dermatology*, May, 1908) adds another to the list of acute cases of lupus erythematosus associated with nephritis, and having a fatal issue. The patient, a girl, æt. 17, was admitted to hospital in the beginning of August, 1907, with well-marked and typical evidence of the disease on the face and on the hands. The first appearance of the disease was noticed three months before admission to hospital. The patient was treated with salicin internally, 15 grains twice daily, and locally with Hebra's soap spirit lotion. The local condition improved very quickly, so that by November the 7th the lupus erythematosus had practically disappeared. The patient's general condition was not so good, and she complained of headache, morning sickness, and swelling of the legs. The urine was found to contain a large quantity of albumin. The patient died on December the 3rd, and at the time of her death she had profound anæmia, œdema of the ankles, and some purpuric spots on the feet. No post-mortem examination was made. K.

Asylum Workers' Association.

THE annual general meeting of this Society will be held at the rooms of the Medical Society of London on Friday, May 29th, at 3.30 p.m., Sir William J. Collins, M.D., F.R.C.S., M.P., President of the Association, in the chair. Dr. Robert Jones, F.R.C.P., Medical Superintendent L.C.A., Claybury, will give an address as Vice-President, and the following have intimated their intention to take part in the meeting:—The Lord Bishop of Barking, Sir James Crichton-Browne, M.D., F.R.S., Sir John H. Bethell, M.P., Dr. V. H. Rutherford, M.P., Drs. Hyslop, Savage, Percy Smith, and members of the Executive Committee. There will be a presentation of two gold and three silver medals, awarded by the Association for long and meritorious nursing service. All interested in asylum work and workers are cordially invited to attend.

IT has been officially stated that there were 793,000 deaths in France last year, as against 773,000 births. This state of affairs points to an extremely acute phase of the question of the limitation of births upon population.

A SERIOUS outbreak of cholera has prevented the 1st Battalion of the Royal Munster Fusiliers from joining the expedition into the Mohmand country under Major-General Sir James Willcocks. Twenty-seven deaths were reported on the 18th inst.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

THE IMAGINATION PATHOLOGIC.

In the new edition of Tennyson's works it is stated that he once heard a nightingale singing with such a frenzy of passion that it was unconscious of everything else, and not frightened though he stood close beside it. "I saw its eye flashing, and felt the air bubble in my ear through the vibration."

Pestis.—The plague mortality in Bombay, the United Provinces and Punjab during January, 1907, was 44,319; this year it was 7,445. In February of last year the plague deaths in this area were 78,063; this year they were 11,898. If we take the totals for the whole of India the results are: For January and February of 1907, 122,382; for the first two months of this year, 18,343. Unfortunately it is true that since the end of February the plague mortality has risen, and during March it averaged nearly seven thousand a week; but this is still mild in comparison with the terrible epidemics of recent years.

THE UNCERTAINTY OF LIFE.

From the womb to the tomb the road varies in length,
And it does not depend on the health or the strength.
A short journey for some we considered were strong;
Some drift down the stream, some are hurried along,
Till the river of life finds its way to the sea,
And we're lost in the Ocean of Eternity! A. D.

H. A. Russell.—Your list is an excellent one, but we would suggest the substitution of Prof. Buchanan's "Manual of Anatomy" for the other, as it is both systematic and practical, and includes embryology.

A WAY THEY HAVE IN THE NAVY.

A candidate who applied for the appointment of medical inspector of schools under the Edmonton Education Committee, when interviewed, mentioned that he was for two years in the Navy. Asked why he left, he replied, amidst laughter, "I used to work about five minutes a day, and I was afraid that if I stayed too long I should get used to it."—*Daily News.*

Mal-de-Mer.—There is a new invention for the prevention of sea-sickness. It is composed of a machine like a Luge spinning-top. On this the patients lie, and are spun round at a sufficient speed to keep it fairly perpendicular. The experiments, which have been carried out at Stettin, are said to have been successful, but the views of the patients do not appear to be known.

PREHISTORIC TUBERCULOSIS.

Dr. Paul Bartels says that he has discovered unmistakable traces of tubercular disease in the spinal column of the skeleton of a male belonging to the later Stone Age and found at Heidelberg recently, and that he can conclude with certainty that the man had suffered from tuberculosis. The only vertebræ showing traces of caries were those near the chest; they are in such a state that they point conclusively to tuberculosis. This is the oldest case of tuberculosis which has been discovered yet in Germany.

Meetings of the Societies, Lectures, &c.

Thursday, May 21st.

Royal Society of Medicine (Dermatological Section) (20, Hanover Square, W.).—5 p.m.: Cases: Dr. Radcliffe-Crocker: (1) Mycosis Fungoides (private); (2) Case for Diagnosis (private). Dr. Adamson: (1) Nodular "Ringed Eruption" (Granuloma Annulare); (2) Small Follicular Syphilide. Dr. Whitfield: A Case of Disseminated Lupus with Chronic Lymphangitis of the Face and Osteo-arthritis. Dr. Sequeira: Two Cases of Scleroderma. Dr. Parkes Weber: ? Multiple Xanthoma of the Face of the Diabetic Type in an Infant. Dr. Graham Little: (1) Varus Nodulosis (Brooke); (2) Pseudopelade (Brocq); (3) Pseudoxanthoma Elasticum.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. T. G. Stewart: Syphilitic Affections of the Spinal Cord.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); X-Rays. 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Throat Operations (Mr. Carson).

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Poynton: Pyo-pericarditis.

Friday, May 22nd.

Royal Society of Medicine (Epidemiological Section) (20, Hanover Square, W.).—8.30 p.m.: Paper: Sir Frederick Treves, Bart., G.C.V.O.: Preventive Medicine in Panama.

Society for the Study of Disease in Children (11, Chandos Street, Cavendish Square, W.).—5 p.m.: Wightman Lecture:—Mr. W. Cheyne: On the Defensive Arrangements of the Body as illustrated by the Incidence of Disease in Children and Adults.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Dr. StClair Thomson: Clinique. (Throat.)

Saturday, May 23rd.

British Balneological and Climatological Society (Harrogate).—Meeting.

Appointments.

Butler-Smythe, A. C., F.R.C.S.Edin., Surgeon to In-patients at the Samaritan Free Hospital for Women, London.

Campbell, R. B., M.B., C.M.Edin., Medical Superintendent of the Larbert Asylum.

D'Alton, J., L.R.C.P. and S.Irel., Medical Officer to the Birr Board of Guardians.

Fremantle, F. E., M.B., M.Ch., F.R.C.S.Eng., D.P.H., Medical Officer of Health to the Hertfordshire County Council.

Keep, A. Corrie, M.D., M.C.Edin., has been appointed Surgeon to In-patients at the Samaritan Free Hospital for Women, London.

Lister, T. E., M.B., Ch.B.Vict., Resident Obstetric Officer at the General Infirmary, Leeds.

Morison, F. H., M.D., C.M.Edin., D.P.H., Medical Officer of Health to the Cumberland County Council.

Pickles, P. D., House Physician at the General Infirmary, Leeds.

Scargill, H. B., M.B, B.S.Lond., House Physician at the General Infirmary, Leeds.

Tebbs, B. N., M.D.Cantab., Assistant Physician to the Royal South Hants and Southampton Hospital.

Vacancies.

Leeds General Infirmary.—Resident Medical Officer. Salary £150 per annum, with board, residence, and washing. Applications to the Secretary of the Faculty at the Infirmary.

Leeds General Infimary.—Resident Ophthalmic Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary of the Faculty at the Infirmary.

Hull and Sculcoates Dispensary.—Medical Officer. Salary £210 per annum net. Applications, J. E. D. Stickney, Hon. Secretary, Crown Chambers, Land of Green Ginger, Hull.

City of Edinburgh.—Medical Officer of Health. Salary £800 per annum. Applications to Thomas Hunter, W.S., Town Clerk, City Chambers, Edinburgh.

Durham County Council.—Assistant County Medical Officer of Health. Salary £300 per annum, with reasonable travelling expenses. Applications to Ralph Simey, Clerk of the County Council, Shire Hall, Durham.

Inverness District Board of Lunacy.—Medical Superintendent for the Inverness District Asylum. Salary £500 per annum, with free house, fire, light, vegetables, and keep of one horse. Applications to Duncan Shaw, W.S., Inverness, Clerk to the District Board.

Births.

Hall.—On May 16th, at 19, Collegiate Crescent, Sheffield, the wife of Arthur J. Hall, M.D., F.R.C.P., of a daughter.

Peatson.—On May 13th, at 211, London Road, Croydon, the wife of J. C. S. Peatson, M.R.C.S., L.R.C.P., of a daughter.

Roberts.—On May 13th, at 128, Commercial Road, Portsmouth, the wife of Hamilton A. S. Roberts, M.D., of a son.

Marriages.

Cooper—Brennan.—On May 14th, at Wimbledon Parish Church, Edward Cooper, Fleet Surgeon, Royal Navy, H.M.S. "Swiftsure," youngest son of the late Alfred Cooper, Esq., of "Southampton Villa," Southsea, to Margaret Wilhelmina, daughter of the late Rev. William Brennan, M.A., some time Rector of Ballysadare, County Sligo.

Hall—Biron.—On May 13th, at Suva, Fiji, Frederick Hall, L.R.C.S. and L.R.C.P.Dub., eldest son of Lieut.-Colonel Frederick Hall, the Connaught Rangers, of Lisnaloe, Emsworth, to Mona, daughter of Rev. H. B. Biron, M.A., vicar of Lympne, Kent.

Lamplough—Eastlake-Smith.—On May 13th, at St. Bartholomew's Church, Sydenham, Wharram H. Lamplough, M.D., of Bredon, Alverstoke, Hants, to Gladys Shirley Eastlake, only daughter of Charles Eastlake-Smith, of Fairbank, Sydenham, Kent.

Deaths.

Raikes.—On May 12th, at Singapore, Cuthbert Taunton Raikes, M.B.Oxon. (Colonial Medical Service), of plague contracted while performing a post-mortem examination, son of Robert Taunton Raikes, of Treberfydd, Breconshire, aged 29.

Mellin's Food

Rich in Flesh, Nerve, Brain, and Bone Formers.

THE ANALYSIS OF MELLIN'S FOOD SHOWS IT TO BE :—

1. Absolutely Free from Starch.
2. Free from Glucose or Cane Sugar.
3. Rich in Maltose, the analogue of lactose.
4. Alkaline in reaction.

Mellin's Food contains no dried milk and is anti-scorbutic. It modifies cow's milk, and makes it chemically and physiologically identical with breast milk.

Complete Tables of Analyses and Samples will be forwarded free to Members of the Medical Profession on application to MELLIN'S FOOD, LTD., Peckham, London.

SCHERING'S

Beta-Eucain-Lactate

The Local Anæsthetic par excellence.

Possesses all the advantages of Beta-Eucain Hydrochlor. over Cocain, but in addition is readily soluble up to 20 p.c. Can be sterilized by boiling. Toxic effects reduced to a minimum.

SCHERING'S

Urotropin

Hemaboloids ARSENIATED (with Strychnia)

restores Iron Equilibrium, furnishes material for and promotes nutrition, inhibits Katabolism and Hemolysis, is antiperiodic, tonic and stimulates the Brain, Cord and Sympathetic Nervous System. Is in stable combination, palatable, does not irritate the gastro-intestinal tract, non-constipating, readily and promptly assimilated without action upon the teeth.

One tablespoonful represents the equivalent of

Tr. Ferri Chlor.	-	20 Minims
Arsenious Acid	-	1/40 Grain
Strychnia	-	1/80 Grain

Indicated in the severest forms of Anemia, especially that of Chronic Malarial Poisoning, Cachexiae, Malignant Disease, Sepsis, Chorea, Chronic Rheumatism, Obstinate Neuralgias, after Operation, Protracted Convalescence, etc.

Valentine's Meat-Juice

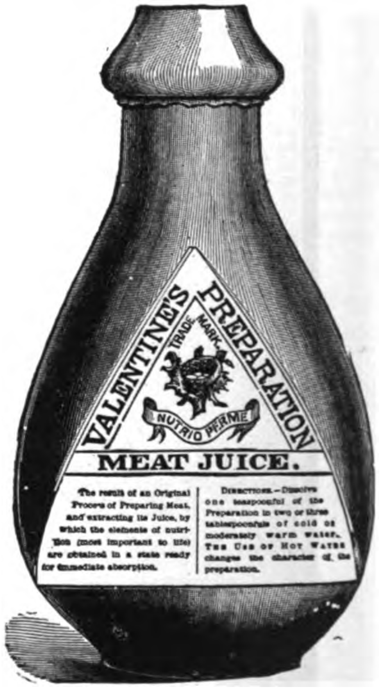
For **Ease of Assimilation, Nutrition** and **Stimulation,** for **Power in Sustaining, Restoring** and **Blood-Building,** when other foods fail, in the treatment of **Gastric** and **Intestinal Troubles, Febrile Conditions** and **Wasting** and **Debilitating Diseases,** Valentine's Meat-Juice is extensively employed by well-known European and American physicians

In Hospital Practice.

A. Reeves Jackson, M. D., *President and Professor of Gynaecology, College of Physicians and Surgeons, Chicago; Surgeon in Chief Woman's Hospital of the State of Illinois, U. S. A.:* "Our hospital is devoted exclusively to the treatment of the Special Diseases of Women, and many of the cases, through long suffering, become anæmic, debilitated, and have feeble digestive powers. These do not so much need drugging as they do a full supply of easily digestible, blood-making food in the smallest bulk. This need Valentine's Meat-Juice admirably supplies, and thus far we have not found a single case in which it was not beneficial and did not agree with the stomach."

Prof. Dr. M. Dufour, *Physician to the Ophthalmic Hospital, Lausanne, Switzerland:* "I have recently found Valentine's Meat-Juice most useful in the case of a child suffering from Appendicitis. I frequently prescribe Valentine's Meat-Juice, and have done so ever since it was used most successfully in the treatment of a member of my own family when he was ill some years ago."

W. S. Tremaine, M. D., *Professor of Surgery, Niagara University; Consulting Surgeon Maternity, Emergency and St. Francis Hospitals, Buffalo, N. Y.:* "I have much pleasure in stating that I have used Valentine's Meat-Juice for more than ten years and can testify to its excellence. I know that I have saved lives with it when every other form of nourishment was rejected. It is a most valuable preparation, and I constantly use it."



VALENTINE'S PREPARATION
TRADE MARK
NUTRIO PERME
MEAT JUICE.
The result of an Original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition (most important to life) are obtained in a state ready for immediate absorption.
DIRECTIONS.—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or moderately warm water. THE USE OF HOT WATER changes the character of the preparation.

Physicians are invited to send for brochures containing clinical reports.

For Sale by European and American Chemists and Druggists.

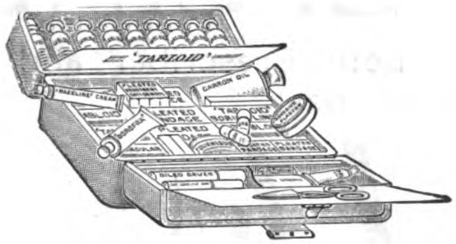
Richmond, Va., U. S. A.

TRADE MARK **'TABLOID'** BRAND

FIRST-AID

For

Automobilists
Aeronauts
Yachtsmen
Sportsmen
Travellers
Tourists, etc.



No. 702 'Tabloid' First-Aid
7 × 5¼ × 2⅝ in.

Compact equipments of first-aid dressings and drugs for emergency use.

Reliable outfits for the physician to recommend to patients about to travel.

The medicinal contents can be adapted to enable patients to continue a prescribed course of treatment.

Cases and contents are of the B. W. & Co. sterling quality.

LIST

No. 702 'Tabloid' First-Aid
(Registered)

Contains *eight* tubes of 'Tabloid' and 'Soloid' Brand products, 'Borofax,' 'Hazeline' Cream, Sal Volatile, Carron Oil, 'Tabloid' Bandages and Dressings, pins, scissors, etc., etc.
Measurements, 7 × 5¼ × 2⅝ in.

In Rex Red, Royal Blue, or Brewster Green Enamelled Leather 50/-

No. 703 'Tabloid' First-Aid
(Registered)

Contains *nine* tubes of 'Tabloid' and 'Soloid' Brand products, 'Borofax,' 'Hazeline' Cream, Sal Volatile, Carron Oil, 'Tabloid' Bandages and Dressings, pins, scissors, etc., etc.
Measurements, 8 × 6 × 3 in.

In Rex Red, Royal Blue, or Brewster Green Enamelled Leather 80/-

No. 722 'Tabloid' First-Aid
(Registered)

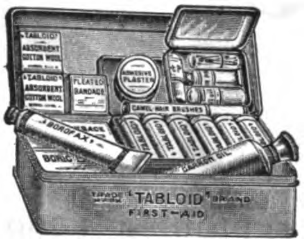
Contains *eight* tubes of 'Tabloid' and 'Soloid' Brand products, 'Borofax,' 'Hazeline' Cream, Sal Volatile, Carron Oil, 'Tabloid' Bandages and Dressings, pins, scissors, etc., etc.
Measurements, 6¾ × 4¾ × 2½ in.

In Rex Red, Royal Blue, or Brewster Green Enamelled Metal, or in Aluminised Metal 25/-

No. 723 'Tabloid' First-Aid
(Registered)

Contains *nine* tubes of 'Tabloid' and 'Soloid' Brand products, 'Borofax,' 'Hazeline' Cream, Sal Volatile, Carron Oil, 'Tabloid' Bandages and Dressings, pins, scissors, etc., etc.
Measurements, 8 × 5¼ × 2½ in.

In Rex Red, Royal Blue, or Brewster Green Enamelled Metal, or in Aluminised Metal 35/-



No. 707 'Tabloid' First-Aid
6½ × 3½ × 2 in.

NO OTHER PEPSINE

Has given so great satisfaction to both Prescriber and Patient for twenty years past.

Schacht's Fluid Pepsine

PEPSINA LIQUIDA
(SCHACHT).

One Teaspoonful will Peptonise 1,000 grains of Albumen.

The LANCET reports: "The preparation is decidedly elegant, and possesses great therapeutic powers."

The BRITISH MEDICAL JOURNAL says: "We find by experiment that it has the peptonizing power claimed for it by the makers."

The PRESS & CIRCULAR, October 10th, 1900: "On applying the test to Pepsina Liquida the albumen was completely converted, thus fulfilling the manufacturers' claim. The flavour of the preparation is particularly agreeable."

THE ADULT DOSE IS A TEASPOONFUL, WITH FOOD. REACTION, ACID.

In 4 oz., 8 oz., and 16 oz. bottles, of every Wholesale House,
OR DIRECT FROM

GILES, SCHACHT & Co., CLIFTON, BRISTOL.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, MAY 27, 1908. No. 22.

NOTES AND COMMENTS.

Medical Suffragettes.

WE read with a good deal of shame and disgust that among the suffragettes who took part in the latest vulgar escapade directed against the Prime Minister were two medical women. One of them was not arrested, but the other one, Miss Elizabeth Knight, M.B., was taken into custody by the police, and after the usual police court performance, sent to Holloway in default of paying her fine. The case will no doubt be reported to the General Medical Council by the police authorities in accordance with the standing arrangement that exists, and we trust that body will show that there is little sympathy in the profession with those of its members who can so far forget the respect due to the dignity of their calling as to indulge in obstreperous behaviour on the doorsteps of gentlemen's houses, be they Ministers or more humbly-placed individuals. There is nothing " political " in women masquerading as Apaches; it is mere hooliganism, and quite inexcusable under any circumstances, but for those members of the sex who belong to the profession of medicine, which demands at least a certain public decorum in its members, to engage in deliberately-provoked street brawls is disgraceful in the highest degree. The theatrical " martyrdom " which persons of the type affect can call forth nothing but disgust among those who have the good name and fame of the medical profession at heart.

Declining Birth-Rate.

THE further fall in the birth-rate disclosed in the recently-published Registrar-General's returns for 1907 has led to the usual display of fireworks in the correspondence columns of the press. That the nation is foredoomed to sink to the level of a second-class power is the least of the evils prophesied by our Jeremiahs, and one is left to infer that no man or woman has done their duty to the State till the largest number of procreations of the species have been effected by him. Indeed, these good people apparently take the view that the country is a kind of Franco-British Exhibition, into which the largest number of individuals must be hurried in the shortest possible time, irrespective of their temporal or spiritual welfare. We do not wish to argue that there are not evils in bachelordom or spinsterhood, or late marriages, or limited families, nor is it wholly encouraging for the birth-rate to fall, as has been the case in London, from 36.5 to 28.8 in forty years, but the fact remains that the highest birth-rate, the highest infantile mortality, and the highest general death-rates almost invariably go hand in hand. Dublin enjoys the pre-eminence of being about the most unhealthy European city, and it is the only one in which the birth-rate has actually increased in the last twenty years. Although selfish and sordid motives mingle with other and higher ones, the present general lesson would seem to be that where care, forethought and prudence are exercised in the raising of children, the number of young ones is not indiscriminately raised for the mere sake of loading the olive tree with branches, and that the future development of man is likely to take place on other lines than that of weeding out the unfit by the slaughter of the weaklings.

Schoolmasters' Liability.

IT is so frequently one's unpleasant duty to chronicle cases in which through some *hiatus* in the law or through some mode of trickery, medical men are deprived of their fees for attendance, that it is a relief to turn to one in which a medical man succeeded in establishing a claim which theoretically exists, but is hard practically to substantiate. At the Clerkenwell County Court the other day the headmaster of a school was sued by a medical man for attendance on one of his pupils. The boy was taken dangerously ill, but by the doctor's exertions and skill his life was saved, and recovery eventually became complete. The boy's guardian was in Paris, and telegraphed to say, " Spare no expense. Have everything necessary," but when the time came to pay he took no notice of the letters written to him. As the doctor had been summoned by the headmaster, he told that authority that it was to him he must look for payment; but still no fees were forthcoming. The action, therefore, was entered, and defended on the ground that the schoolmaster disclaimed all authority in the matter. Judge Edge remarked, very wisely that in the case of a boy living with a schoolmaster, the latter was bound to call in medical assistance, and could only rid himself of responsibility by informing the doctor that he would not be liable for any further attendance. Judgment, therefore, was given for the plaintiff. Although this result may seem rather hard on the defendant, it is clear that it is more just that the onus of recovering expenses incurred by a boy should fall on a schoolmaster, under whose charge the lad is than on the doctor who has no hold of any kind on the parent; the former at least has the boy and his belongings to hold as hostage.

Medical Certificates in the Law Courts.

WE have several times urged that an official medical man should be attached to every court of law to certify, when ill-health is alleged, whether persons summoned to appear are or are not in a fit state to obey their subpœnas. The plan of requiring a certificate from the patient's own attendant throws an invidious responsibility upon him in many cases, and lays his *bonâ fides* open to most unpleasant criticism in court and among the other interested parties. A curious case of the kind occurred the other day at Cheltenham County Court. A woman was subpœnaed against her will to give evidence in a certain case, and along with her letter saying her evidence would be no good, she enclosed a medical certificate to say she was unfit to attend the court. The solicitor thereupon wrote to say that the doctor's certificate was no good unless an affidavit was sworn, and that he would apply for the woman to be committed for contempt of court. Consequently an affidavit was sworn by the doctor in due form, and the expenses attendant thereon sent to the solicitor, who refused to pay. An action was consequently brought against him, and the Judge very properly said that a medical certificate without an affidavit was quite sufficient, but that as the solicitor insisted on the affidavit he would have to pay for it. The defendant said this was a "new and novel" point of law on which he should like to appeal, but his demand was refused. As usual, remarks were made as to ulterior motives operating, and we cannot but think that the duty in these cases should not devolve, at any rate wholly, on the private medical attendant.

Methylene Blue and Thieves.

A little knowledge may be a dangerous thing, but a little elementary chemical knowledge may be very useful at times. The nurses at the London Hospital having been annoyed by thefts of small artticles from their rooms, hit on an ingenious plan last week. A purse containing several coins was treated with methylene blue, and the coins likewise, and then put away in a cupboard where it was suspected the thief would pry. In due time it was missed, and in the room of the suspected party were found a towel, a pair of gloves, and a handkerchief, all stained with that sturdy and penetrating dye. The owner of the stained articles stoutly denied the theft, but could not account for the cerulean hue of her linen, and she was haled before the magistrate in consequence. In court she broke down and pleaded guilty, and as her hospital record was an excellent one she was treated under the First Offenders' Act. This item of chemical knowledge thus brought into prominence may be found of value by Scotland Yard, which, in spite of its responsibilities, is in many ways far less scientific than the experts whose doings it is its duty to reveal.

Millionaires and Rabies.

One of the most patent facts in life is that people in this country love a lord, and it is equally true that in America they love a millionaire. This is not the place to discuss which is the more amiable, the aristocrat or the plutocrat, but it is certain that however much rank tells on this side, the populace do not throw themselves into frenzied transports whenever a lord is discovered in forgery, or suffers from an illness of a commonplace nature. Great excitement prevailed in New York last week over a Mr. Marsh, whose great title to fame was the possession of a successful manufacturing business. This gentleman had a dog suffering from rabies, and he became infected with the complaint through attending to the animal. It was not till the symptoms were well developed that the disease was diagnosed, and at the Pasteur Institute he was refused treatment, as it was too late to hope to do any good. The unfortunate gentleman returned home and died in a day or two. In the course of his brief illness it is stated that the Medico-Legal Society of New York went so far as to file charges against the Pasteur Institute before the District Attorney, on the ground that the nature of the illness was doubtful, and that the patient was dying of opium poisoning administered by his attendants. The post-mortem examination showed that the correct diagnosis had been made at the Institute, and that Mr. Marsh had died of rabies. The whole affair has been trumpeted about in the papers in the best "New York Sewer" style, and it is difficult to know what to believe. But the action of the New York Medico-Legal Society seems incomprehensible.

LEADING ARTICLES.

HOUSING.

The housing of the nation is clearly a matter of supreme importance in relation to the public health. The two things are inseparably united in the sense that the less is contained in the greater. To grasp this connection is to throw both into proper perspective and to realise more accurately a relationship that is apt at times to be somewhat undervalued. So far as the actual housing of the nation is concerned at the present moment, it is hardly too strong a statement to make if we assert that the natural law whereby good housing is rendered essential to a proper maintenance of the public health might almost as well be non-existent for the influence it has upon our social environment. For what are the facts of the case? In spite of Housing Acts and Public Health Acts, we find a fifth of the population of the United Kingdom living in slumdom. There are some eight millions of our fellow-countrymen existing under conditions that are not only a disgrace to our boasted civilisation, but constitute a continual danger to the safety of the community. This is the section of our population declared by Mr. Sidney Webb to be "housed, washed and watered worse than our horses." Yet this deplorable state of affairs persists in spite of numerous well-intentioned efforts of the legislature. That it is due to some defect in our social administration seems clear enough, for no sane persons would voluntarily elect to live in bad in preference to good houses. Nothing clears a slum more effectually than the plentiful provision of good dwellings: it is Hobson's choice that forces the poor into noisome and over-crowded tenements. The whole question has been recently discussed by an able writer in *The Nation,* Mr. George Haw. He points out in a forcible way what he describes as a defect in Mr. John Burns' Bill, namely, the failure to include the far-reaching adaptation clauses of the original Shaftesbury Act of 1851. The central principle involved is that in and around the centres that drift into slumdom are many solid old-fashioned houses that have been divided into tenements, with a family to each floor, or in some cases to each room. Such buildings are clearly unfitted for such sub-division as regards kitchens, water supply, sanitary conveniences, rubbish disposal, ventilation—in a word, they are wanting in all the decencies and essentials of a self-respecting household economy. Yet it would be possible, without any great expenditure of money, to convert such dwellings into first-rate flats, for that is what they would virtually become. The simple addition of an outstanding wing, containing kitchen, bathroom and lavatory accommodation, with the provision of a rubbish shoot and good staircase ventilation, would transform a series of slum tenements into respectable, if not ideal, dwelling quarters. Lord Shaftesbury recognised this possibly when he laid it down as essential that the local authorities be given power to renovate existing dwellings, as well as to build new accommodation. Giving evidence before the Housing Commission thirty-three years later, he was compelled to admit that the local authorities had not given his Act a trial. Mr. Haw quotes his further statement to the Commission: "If you were to look at the terms of my Act, you would see that it would meet everything that is required at the present moment." Could the illustrious philanthropist return to Parliament, he would find to his sorrow that Mr. Burns has ignored the far-reaching adaptation clauses in the Housing Act of 1851. Happily, experience is not wanting to show that such a proceeding is both practical and advantageous. One London local authority has carried out the principle of adaptation on a large scale, and has been able thereby to transform a slum-quarter that was the despair of Charles Booth into a healthy, law-abiding district, and that without displacing a tenant or raising the rents. The two last-mentioned facts, be it noted, constitute the great rocks ahead in all attempts to provide housing for the working classes by municipal enterprise. The credit of this achievement is due to the Camberwell borough Council, which now owns over 500 tenements, all having been adapted under Part III. of the Housing Act. The value of this object lesson to future legislators is incalculable. It is to be hoped that the question of adaptation will be brought pointedly before the attention of the House of Commons during the consideration of the Bill introduced by Mr. John Burns. That measure is admittedly open to amendments of a manifold and far-reaching nature. Now that the matter has been so ably raised in the public press, we may rest content that it will secure a due amount of consideration from the author of the new Act. Meanwhile the question of housing may be profitably discussed by the various bodies concerned with public health, for in spite of the great strides made in the scientific study of that subject, the lamentable fact remains that eight millions of our population are at the present moment permitted to dwell under conditions that constitute a blot upon our social system.

CURRENT TOPICS.

The Medical Examination of Engine Drivers.

Not many weeks have elapsed since the desirability of instituting a periodical examination of certain railway men, principally engine drivers, stokers, and signalmen, was urged in these columns. It is clear that these men cannot be expected to perform properly the arduous and exacting duties demanded of them unless they be in a state of perfect physical health. Then, again, the hours of labour exacted from every one of the classes under consideration are so long as to lay an undue tax upon human endurance. Only last week the engine driver of an express train died on the footplate a few minutes after leaving Newcastle. A coroner's jury found a verdict of fatty degeneration of the heart, and the Coroner suggested the advisability of a periodical examination of engine drivers and firemen. Quite recently the railwaymen made an indignant public protest because it was suggested that an engine driver had fallen asleep for a few minutes and had thereby caused an accident. Without going into the merits of any particular case, it may be stated broadly that it is a natural sequence of events for an overworked man to fall into a state of partial or of total somnolence for a few moments. It would be far more to the point if the railwaymen were to insist on a reasonable maximum limit of hours of labour, both consecutively and cumulatively. For their own interest, moreover, it would surely be advantageous to be under constant medical supervision, for no man is competent to judge of his physical state of health. In our own opinion, a step of the kind is urgently needed for the protection of the travelling public.

Red Tape and Pneumonia.

Early in the present month a tragic occurrence reported from Middlesbrough suggests the need of sweeping reforms in the methods of Poor-law administration pursued in that town. The facts of the case are simple, but they present a picture that could hardly be surpassed in the worst days of bumbledom. A man was seized with pneumonia at a common lodging house where he was staying, and was promptly ordered by a medical man to be taken in a cab to the workhouse infirmary. He was put, however, in a tramcar, and had some distance to walk to the workhouse. There he found he had mislaid the doctor's order, and was refused admission. On returning to the lodging-house he found the order, which he handed to the lodging-house deputy, and then, to quote the newspaper report, "being exhausted, he lay down and died." The jury returned a verdict of death from pneumonia, but expressed their regret that there had not been more consideration shown to the man at the lodging-house and at the workhouse. It is to be hoped that the Local Government Board will not permit the matter to stop here. If the facts be as reported the man's life has, in all probability been sacrificed to the iron-bound rule which would not admit him at once to the infirmary. To send away a man suffering from pneumonia, whether he have an order or not, is to commit an act of gross inhumanity. Surely it would be the right course to admit any obviously serious case at once into a Poor-law infirmary, and to get the order, if necessary, later. In the present instance, the order had actually been granted, but a man suffering from pneumonia could hardly be expected to look after details, or, indeed, to be in a fit state to take care of anything at all. The Local Government Board may well make a public inquiry into the whole Poor-law medical administration of Middlesbrough. Any organisation that could send a man suffering from pneumonia to hospital in a tramcar stands self-condemned. Why was not the patient taken in a cab?

The Position of Professors of the Queen's Colleges in Ireland.

The position in which existing professors of the Queen's Colleges in Ireland will be placed should the Irish Universities Bill become law has been so far most uncertain, and consequently considerable anxiety has been felt, especially in the Colleges at Cork and Galway. During the past week, however, some information has been forthcoming. In reply to Mr. Featherstonhaugh, who asked the

Chief Secretary for Ireland whether, in withdrawing the charter under which the Queen's Colleges were constituted, and introducing a new charter, it is intended to give those professors of the Queen's Coleges who do not care to take service on the new terms an opportunity of retiring on fair terms as to pension as was done in the case of some officers of the late Queen's University in Ireland, Mr. Birrell said that the existing professors will be offered equivalent posts in the reconstituted colleges, but it is not proposed to give them compensation if they should not choose to accept such equivalent posts. He thought Mr. Featherstonhaugh would find no option was given in the cases to which he referred. The enactment governing those cases appeared to be the Universities Education (Ireland) Act, 1879, section 14. Mr. Birrell has further given notice of his intention to move a new clause in Committee providing that if any existing officer holding his existing office during the pleasure of His Majesty or the Lord Lieutenant, is offered and accepts an office in either of the two new Universities, or in any of the constituent Colleges, he shall hold the office which he accepts on a similar tenure.

Guardians and Medical Salaries.

The inadequacy of the average medical income is one of the standing subjects of discussion in the professional journals. Nowhere is it better illustrated in the shape of a striking object-lesson than in the case of various Poor-law medical appointments. A particular instance is reported in the *Birmingham Post* of the 12th instant, wherein the proceedings of the Aston Board of Guardians are recorded. It was proposed to raise the salary of the medical officer of the Sutton Coldfield District from £50 to £80 per annum, and of the Erdington District from £50 to £70. The proposal was vigorously opposed by a member, who urged that if the Board practised economy in the wages of a gardener and of a boiler attendant, they must do so equally in the case of doctors. After some discussion the proposed addition to salaries was adopted. When compared with an ordinary surgical fee of fifty or a hundred guineas, it seems preposterous to ask a member of a highly skilled profession to give a whole year's arduous and responsible work for the paltry sum of £50 or £80. If we turn to the law, we find barristers receiving a fee of one hundred guineas a day as a "refresher," in addition to a huge sum of money paid down at the outset as a "retainer." It is certain that nothing will ever secure better remuneration for the rank and file of the medical profession except through the agency of a united organisation. The lack of initiative in the Local Government Board does not encourage the hope that Government will interfere with the object of securing "fair wages" for Poor law medical men. Indeed, the only recent action of that Department has been to curtail vaccination fees to a most illiberal and inadequate scale.

A Death under Anæsthesia.

Now that the authenticity of statistics of deaths under anæsthesia has been called in question, thanks to the Coroner for the City of London, we may hope for more accuracy in dealing with the matter. Opportunities for investigation are, unhappily, only too abundant. The fallacies surrounding the subject, however, are of manifold origin, some of them being quite apart from fatalities. Last week a death occurred under ether at the Miller Hospital, Greenwich. The operation consisted in the removal of an abdominal tumour, and during its performance two ounces of ether had been administered. Post-mortem showed healthy organs, if we except the "flabby" heart well-nigh inseparable from these enquiries. Death was ascribed to heart failure, owing to the sudden alteration of blood pressure consequent on the removal of the tumour. The Coroner stated that this was only the second death under anæsthesia that had occurred in that particular hospital since it was founded twenty-five years ago. If that be the case, the record is not a little remarkable, for we have reason to belive that a good amount of surgery has been undertaken at that institution. It would be interesting to learn the details of these two deaths, especially as one was under ether. Further, has the hospital an absolute record of every occasion upon which an anæsthetic has been administered? If so, the figures would have a considerable value. In any case, should the statement as to the two fatalities be correct, and it be further known that a large number of administrations of anæsthetic drugs have been made, the computive issues thereby raised would be of grave public import. The point to be ascertained, both for the safety of the public and the scientific education of the medical profession, is why there should be more deaths under anæsthesia in some institutions than in others, apparently administered under similar conditions.

The Research Defence Society.

We are glad to hear that the recently-founded Research Defence Society is gaining many important adherents all over the kingdom. The object of the Society is to educate the public in the questions regarding scientific research, and in the advantages to the community arising from the encouragement of research. It is not merely an agency to counteract the pernicious effects of the various anti-vivisection societies—though this will not be the least of its activities. In this respect there is no doubt that its teachings are badly needed, for many people are prejudiced against scientific research because they have only heard the arguments against it. The anti-vivisectionists conduct their campaign with sufficient noise, and it is right that some society should be ready to expose their misrepresentations. As regards research in general, moreover, the English public is singularly ignorant, and, in consequence, research in these countries is practised under great difficulties. Rich endowments are necessary, and the country should learn that money spent in this way is often one of the wisest investments.

Society for the Destruction of Vermin.

The present is emphatically the age of societies. Every fresh phase of our complex civilisation, from the fine arts to ping-pong and diabolo, demands its formal association. One of the most recent additions is a society for the destruction of vermin. The definition of the term "vermin" appears to be elastic enough to include rats, mice, fleas, mosquitoes, and house flies. Probably, if there is one point on which mankind is ever likely to approach unanimity, it is as to the desirability of exterminating the common rat. Even in the chambers of the most rabid anti-vivisectionist we doubt if any very real protest would be raised in favour of the common sewer rat. Unpopular as the animal was in former days, the discovery of the fact that the rat is the chief instrument in the spread of plague has turned dislike from a passive to an active mood. War is now waged against rats in every civilised country throughout the world. It is well that an energetic society should encourage the campaign against disease-bearing pests of all kinds. At the same time, it seems to be taxing one's sense of humour to be told that rat skins are not commercially profitable. Considering the filthy habits of the creature, it is earnestly to be hoped that the skins will follow the rats to destruction. Nor is the tone of the society raised by a purely gratuitous estimate attributed to its Secretary as to the existence of 20,000,000 rats in the United Kingdom, where they do £5,000,000 of damage annually, and cost £10,000 for repressive measures in London only. If the society can do something to lessen the plague of flies in the land it will deserve a nation's gratitude. Perhaps the statistician who tackled the rats would favour us with an estimate of the number of flies in the United Kingdom during August.

Medical Men and Public Lectures.

WE have commented once or twice during the past few months on the benefits likely to accrue to the community from the teaching of hygiene in the form of public lectures by medical men. It is of great importance that the public should be instructed in the elementary principles of hygiene, and there is no one so competent to give this instruction as members of the medical profession. In the giving of lectures on medical subjects, however, there are certain limitations which are well established by the sense of the profession, and it is necessary at the present moment to draw special attention to them. It is well recognised that details of the medical and surgical treatment of disease are not fit subjects for popular lectures, and that nothing should be admitted which could be regarded as savouring of advertisement of the lecturer's personal skill. It is a matter for deep regret that some of the lecturers in connection with the Women's National Health Association in Ireland are apparently oblivious of these wise restrictions. Thus, last week Dublin had the unedifying sight of a hospital surgeon of good repute lecturing on "The Surgical Treatment of Tuberculosis," and illustrating his lecture by demonstration of patients and apparatus. We have no doubt this gentleman was actuated by the best of motives, but the example is one which we hope will not be followed. The Women's National Health Association owes much of its success to the cordial support it has received from the medical profession. It cannot afford to estrange their friendship by the repetition of indiscretions of this sort.

PERSONAL.

VISCOUNT MILNER will preside at the annual dinner of King's College, London, to be held on June 23rd.

DR. WILLIAM JAMES HOWARTH, Medical Officer of Derby, has been appointed County Medical Officer for Kent.

MR. A. P. PARKER, M.B., F.R.C.S., has been appointed University Lecturer in Applied Anatomy at Oxford.

WE regret to learn that Mr. Francis Fowke, for thirty years secretary of the British Medical Association, has recently died at the age of 68.

VISCOUNT MORLEY, of Blackburn, will be the guest of the evening at the dinner of the Indian Medical Service Officers to be held on June 18th, at the Gaiety Restaurant.

ON May 16th the members of the British Balneological and Climatological Society held a meeting at Harrogate, the President, Dr. W. J. Tyson, of Folkestone, in the chair.

LORD CHEYLESMORE has received from Mr. Charles H. Berners a further contribution of £100 towards the maintenance of the Middlesex Hospital Cancer Charity.

DR. A. E. GARROD will give the Croonian Lectures of the Royal College of Physicians of London next month. His subject will be: "Inborn Errors in Metabolism."

THE members of the Imperial Yeomanry Hospitals Committee, staff, and some of its principal subscribers, have sent £221 11s. towards the "Hall-Edwards" Fund as a mark of appreciation of the services rendered during the African War by Mr. Hall-Edwards.

DR. J. J. BUTTERWORTH, medical superintendent of schools for Salford, has been appointed to a similar position for the County of Lancashire at a salary of £500 per annum, rising by £50 yearly to £650, together with office and the necessary clerical assistance.

THE festival dinner of the West London Hospital was held on May 19th at the Trocadero Restaurant, the Duke of Abercorn, President of the hospital, occupying the chair. The subscriptions received during the evening were announced as £4,254.

ON May 18th Sir Almroth Wright, M.D., F.R.S., was presented with the Fothergill gold medal at the annual *conversazione* of the Medical Society of London. The medal is awarded triennially to a medical man who has done exceptionally valuable work in some branch of practical medicine or surgery. In 1803 the first Fothergill medal was given to Edward Jenner.

A LARGE assembly met at the Cardiff Infirmary, on May 19th, on the occasion of the formal opening of the new out-patient department, which has been erected at a cost of £8,000. Major-General Lee, Chairman of the Board of Management, presided, and he was supported on the platform by Professor William Osler, M.D., F.R.S., who accepted the committee's invitation to perform the opening ceremony.

THE annual dinner of the Pharmaceutical Society of Great Britain was held on May 19th, at the Hôtel Métropole. Mr. J. Rymer Young, the President, occupied the chair, and the company, numbering about 180, included Mr. T. Lough, M.P., Mr. Idris, M.P., Sir R. Douglas Powell, Sir John McFadyean, Dr. W. H. Martindale, Dr. A. Newsholme, Sir B. Redwood, Sir Thomas Stevenson, and the Master of the Society of Apothecaries.

THE PRESIDENT (Mr. Henry Morris), the Vice-Presidents (Mr. Rickman J. Godlee and Mr. W. Watson Cheyne), and the Council of the Royal College of Surgeons entertained at dinner, on May 21st, Viscount Selby, Lord Aldenham, the Treasurer of the Middle Temple (Mr. Justice Phillimore), Mr. Justice Eve, the President of the Royal College of Physicians (Sir R. Douglas Powell), the President of the Royal Society of Medicine (Sir William Church), the Vice-Chancellor of the University of London (Sir William Collins, M.P.), and a large company of distinguished guests.

A Clinical Lecture

ON

HOW TO SET TO WORK IN ORDINARY OBSTETRICAL PRACTICE.

By PROFESSOR R. DE BOVIS, M.D.,

Professor of Obstetrics at the Rheims Medical School.

[Specially Reported for this Journal.]

In spite of the progress that has taken place in obstetrics, and the methodical teaching of which it is the object, it must be admitted that, from the point of view of antisepsis, ordinary obstetrical practice leaves much to be desired. Since a scapegoat must be found, it is necessary to gird at the midwife, and that she plays a conspicuous part for evil cannot be gainsaid. At a distance from hospitals, unable to keep herself abreast of scientific improvements, stuck fast in the chronic filth of the environment in which her work lies, the midwife, especially if advanced in years, is rarely up to the mark. I am, of course, referring to the prophylaxis of infection, for in other respects the service rendered by these modest practitioners is indisputably very great. But things that may be impossible for the midwife are possible for the doctor, and he it is who should preach by example. Yet we are constrained to admit that, as a rule, we fail to fulfil this our duty.

It is to be feared that far too many students quit our lying-in hospitals under the impression that there is nothing worth remembering of all they have been taught, simply because most of it is inapplicable in daily practice, or would prove unnecessarily troublesome. When he is called to his first case of difficult labour, the student, now a practitioner, finds himself in a small, ill-ventilated, ill-lighted room, beside a dirty bed, with, to wash his hands, a bowl instead of a basin, the water for which has been poured from a saucepan dipped into a bucket. Then, indeed, it is difficult to avoid contrasting his hospital experience with the grim reality of general practice. However, he does his best, and manages to deliver his patient in a fairly cleanly manner. All the same, he leaves the bedside feeling certain that his patient will infallibly succumb to acute infection in three or four days, and his relief is great when it turns out otherwise. The first time this happens he is immensely surprised, but ultimately he gets used to it, and ends by looking upon the elaborate precautions enforced in hospitals as somewhat unnecessary. When the time comes, and he loses a patient from puerperal infection, he is prone to attribute it to the heart, kidneys, or lungs of the defunct, and to take very little blame to himself.

I must admit that good old Mother Nature is in a certain measure responsible for the indifference that comes over us. I cannot give you the exact proportion of deaths from puerperal fever in town and country practice, but it is certainly pretty low. When I say low, I mean in respect of the total number, for if we contrast the figure with what it ought to be, it is very high. If we add to this that even a busy doctor only attends a comparatively small number of confinements, it is easy to understand that he may go on for years without seeing a death from infection, and during this time he has been acquiring bad habits, those of the midwife have got worse, and it becomes impossible to go against the current.

This, then, is the root of the evil. It is for you to remedy it; but it will, I fear, be under circumstances and in an environment of a discouraging kind. My present object is to warn you of certain difficulties and to advise you how to obviate them.

The first practical question is how to avert the risk of puerperal fever. You will often be asked by patients belonging to certain classes of society whether it is advisable to make use of injections during the period of gestation. That amounts to asking whether it be possible to lessen the chances of infection by measures taken before labour. The answer is somewhat doubtful; indeed, it does not seem to have been sufficiently thought out. Certain accoucheurs, holding that the vaginal canal of the pregnant woman is aseptic, or at any rate avirulent, disadvise any intrusion into this domain. Others hold that it would be impossible to allow a woman suffering from vaginitis or cervicitis to go to term without any attempt to improve her condition. My own experience inclines me to adopt the latter view.

Our parturient patients belong to two classes: the "expectants," who come several days or weeks before labour is due; and those who are in labour on admission. For women of the first category the maternity is a kind of "waiting-room"; they are servants out of place, deceived and deserted girls, and low-class prostitutes, all persons the state of whose genital organs leaves much to be desired. During 1907 these "expectant" women gave 10 per cent. of febrile cases, whereas the others, who were in labour on admission, gave 11.6 per cent. During the previous year the two classes gave the proportions of 9 and 15.7 per cent. respectively. These "expectants" were duly bathed and subjected to the most perfect genital disinfection possible, so that the slight advantage in their favour, notwithstanding their doubtful sanitary condition, may, I think, be fairly ascribed to the prophylactic measures of which they were the object.

In order to attain this result, however, we must have recourse to very strict genital disinfection. For instance, in 1905, we merely gave injections, and the result was *nil*. Since then the parts are soaped, rubbed, even scraped, and sometimes we leave in a strip of iodoform gauze, with, as you see, somewhat better results. Consequently, in women who are open to the suspicion of genital infection, you will be fully justified, if you get the chance, in adopting preventive measures. In the others this is unnecessary. Unfortunately these precautionary measures are not always available—at any rate in regard to baths; but a hip bath can usually be compassed, and I advise you to advocate its use.

We now come to labour itself. When you get to the lying-in room the first thing is to secure an ample supply of hot and cold boiled water. The former can be had easily enough, but not the latter, so you had better advise your parturient patients never to go to bed during the last fortnight without having boiled a cauldron of water and set it aside to cool. Get as much boiling water as you can—one never has too much of it. Boil your rubber gloves if you have any, as well as the tube and nozzle of the enema, wrapping them in a towel to prevent their being burned. Take advantage of the opportunity to boil your instruments. Then wash your hands.

Whether the patient be rich or poor, this is always a matter of some difficulty. If you ask to wash your hands they hand you the traditional basin half-filled with water and there you are, dabbling in dirty water just before making an examination. Should there be a tap use that rather than the basin, it is far preferable. Another plan, however, is to fill the douche-can with boiled water and, hanging it on the wall, to wash your hands in the running water thereof. After that you can dip them in perchloride solution or spirit, if you please, for you will have accomplished mechanical asepsis, after which all else is more or less superfluous. In any event, never do what I have so often seen done, viz.: to dip your hands for a few seconds in a solution of perchloride before making an examination or proceeding to turn or apply the forceps. You may think you have taken antiseptic precautions, but in such cases the perchloride will have done us very poor service, indeed, it merely cloaks uncleanliness.

Then, too, you will have done nothing to render the external genitals aseptic. This, although universally recommended, is rarely carried out in practice. Yet the necessity for it is obvious. Without it the hands, instruments, etc., are liable to be contaminated by contact with the thighs and the labia, and may carry a whole series of micro-organisms into the vagina. What would you think of a surgeon who proceeded to operate without the least sterilisation of the skin? You must look upon a confinement as a surgical act, to be treated accordingly. The fœtus leaves behind it tears, wounds, and erosions. Therefore imitate the surgeon who disinfects the field of operation before commencing. The difficulty in practice is to accomplish this, but it can be done by the aid of the douche-can, which is always available at present. Hang up the can at the head of the bed. Allow the boiled water to run on to the external genitals, rub the parts well with soap, and in this way you can cleanse the vulva, anus, gluteal region and inner sides of the thighs. Rub well and long, then wash the parts clean with the running water. Then, having cleansed your own hands *de novo*, wipe the parts dry with sterilised cotton.

I have not referred to the use of any antiseptic, but you must not suppose that I disdain their use. I wish to insist first of all on the mechanical agents of disinfection. Nowadays the surgeon relies on little else and you will lose nothing if you follow his example. Is it to be supposed for an instant that a little perchloride solution trickling over the perinæum will remove the fatty layer which is a true culture medium for microbes. At the present time, now that the practice of washing the hands has become general, the great danger of puerperal infection lies in neglecting the toilette of the external genitals. As a matter of fact, even the partially-cleansed hand is vastly less septic than the "'tween leg" region. The hand, it is true, is exposed to many doubtful contacts, but the very frequency of contacts brings about a sort of automatic scraping, whereas nothing of the kind is brought to bear on the region aforesaid. Perspiration, the secretion of the sebaceous glands, vaginal discharges and peri-anal contamination, all contribute to render this region dangerous. Soap will remove all that, and if you can get this done beforehand so much the better, and this is an argument in favour of *ante-partum* baths.

Washing with spirit or ether and scrubbing, on the other hand, are inadvisable, the perineo-vulvar tissues being too tender; in fact, this should only be done on women who are under an anæsthetic. Nothing prevents your washing the parts with perchloride after washing them, but never use the perchloride at the same time as the soap, for they are mutually antagonistic, so that the cleansing process will be incomplete in consequence. When you have finished washing your patient and your own hands you may make use of the soap you have been using to lubricate the fingers. If there be any reason to suspect syphilis, however, a fatty substance is preferable. Beware, however, of pots of vaseline into which fingers have been dipped, and this is why I advise soap. Nor should you make use of salad oil unless you can sterilise it first.

Ought we to make an injection after examining? This is unnecessary if you have made yourself aseptic; nevertheless, if by any chance your patient should be suffering from a genital infection, it may be well to start with a simple injection, but to be of service you will have to rub the vaginal walls with the soaped finger or you will leave them with the microbial colonies as before. On the other hand, an injection made without previous cleansing of the external genitals is likely to do more harm than good. Having in view the importance of keeping the obstetrical field free from contamination, only give an enema at the onset of labour or before the head has come down, otherwise the descent of the head will extrude the remainder of the enema, bringing about more extensive contamination than solid matter would do.

You have now done all that is necessary so far, and you can proceed to prepare for coming events. Select a small table, cover it with a clean towel, and place thereon everything you are likely to want: a large basin of boiled water, another (smaller) containing a solution of perchloride or spirit, leaving your sterilised gloves in basin No. 1. You will thus be enabled to clean your hands as required, for in the houses of the poor there is not always someone at hand to move the bedclothes, etc., hence you are continually liable to contamination. The soap may be left in the spirit or perchloride, it will not dissolve and is thus kept aseptic. In a soup-plate you place a catheter, thread to tie the cord, a hypodermic syringe, a suture needle for ruptures, and some catgut.

You may be surprised at my referring so frequently to spirit—and I mean methylated spirit—as an antiseptic. It is really a very convenient agent, you can leave your hands and instruments therein as long as you like, and it is quite as effectual as the perchloride employed in obstetrical strengths. It is everywhere to be had, at all times of day and night, which is no small advantage in antisepsis. Put half-a-dozen clean towels on your table, some absorbent cotton—in its paper wrapper. Place the table behind the spot where you will be during the stage of expulsion, so that you can reach the things yourself without the risk of their being handled by third persons.

These towels will serve to keep the operating field clean. Theoretically, of course, they ought to be sterilised or boiled, but if boiled your patient would have to come into contact with wet cold linen, apart from the fact that there may be no time for this. Moreover, clean linen is tolerably aseptic, vastly more so than the parturient's own skin. In any case, a clean towel is much more aseptic than the sheet on which the patient has been turning and twisting for hours, and which may be the only one available. Moreover, they are mainly of use at the stage of expulsion when you have to dam up the tide of amniotic liquid, blood, clots and fæces that would otherwise inundate the bed. By interposing the towels you avoid contaminating your hands and prevent contamination of the genitals. Please bear in mind that the absorbent cotton must always be carefully wrapped up and not allowed to lie round on the counterpane, a warning that is by no means unnecessary. I mentioned that it would be well to leave your rubber gloves in the antiseptic-basin. I cannot insist too strongly on the advisability of making use of them. They cannot be employed when examining or operating, but they are invaluable under all other circumstances. With certain precautions it is easy enough to thoroughly cleanse the hands, but it is practically impossible to keep them clean for hours together and it is even less possible for the midwife, who has other, more servile, duties to perform. You may be suddenly called upon to assist in delivery before you have time to clean your hands afresh, whereas, if you put on the gloves, these can readily be cleansed if accidentally soiled, which is not the case with your hands.

You may feel inclined to put a finishing touch by the application of an antiseptic dressing to the vulva, but you would be taking a lot of trouble for very little purpose. It soon gets twisted and uncomfortable, and, if applied, it ought to be moist in order to lessen the risk of perineal rupture. In obstetrics, as elsewhere, "*le mieux est parfois l'ennemi du bien*," and when you have done what is necessary do not further interfere with the layer of amniotic liquid that bathes the vulva, its presence there is to guard against perineal rupture.

May this lecture impress upon you the importance of a refined cleanliness, the daughter of antisepsis, and the superiority of mechanical agents of disinfection, and so disabuse your minds of the fetish of antiseptics. In obstetrics the perchloride is not everything, it does not dispense with the necessity of absolute cleanliness.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Wm. St. Clair Symmers, M.B., C.M. Aberd., Professor of Pathology, Queen's College, Belfast. Subject: "Some Landmarks in the Study of Tuberculosis."*

ORIGINAL PAPERS.

ON THE
DANGERS AND TREATMENT OF MYOMA OF THE UTERUS. (a)

By CHRISTOPHER MARTIN, M.B.Edin., F.R.C.S. Eng.,

Surgeon to the Birmingham and Midland Hospital for Women.

LECTURE I.

The more I see of myoma or fibroid tumour of the uterus, the more impressed am I by the risks of the condition. To-day I propose to call your attention to certain of these dangers, and in my second lecture to discuss the methods of treatment.

Hæmorrhage.—Hæmorrhage from the uterus is the commonest symptom of myoma, and is present in the great majority of cases. It varies much in different cases. In some, with even a large fibroid, it is only a rather profuse or prolonged menstruation. In others, with perhaps quite a small growth, there are terrific floodings. The nearer the tumour to the cavity of the uterus, the more severe the flooding. Thus in the subserous growth it is slight, in the interstitial it is profuse, in the submucous and polypi it is excessive. In some cases, there is a constant dribbling of blood-stained watery fluid, with monthly exacerbations. In others, there are sudden and alarming floodings, with intervals of weeks or months with little or no loss.

It is rare for a patient actually to bleed to death from a myoma. She usually develops a condition of marked chronic anæmia. She has dilated pupils, œdema of the face and feet, loud hæmic murmurs, palpitation, breathlessness, and faintness on the slightest exertion.

Pain and Discomfort.—Uncomplicated myomata do not, as a rule, give rise to much pain; certainly there is nothing approaching the agonies of cancer.

Pressure Symptoms.—The pressure symptoms of myomata are numerous, and frequently call for surgical treatment. Pressure on the rectum causes constipation and hæmorrhoids. Pressure on the iliac veins causes varicose veins of the legs and vulva. Pressure on the sacral plexus of nerves causes neuralgic pains, sciatica, and cramps, though seldom paralysis. Pressure on the uterus may cause backward displacement or even total prolapse of the organ.

By far the most serious and distressing group of symptoms are those due to pressure on the urinary organs.

Lesions of the Ovaries and Tubes.—Disease of the uterine appendages frequently complicates myoma. In some cases, the surgeon opens the abdomen to remove a myoma, and finds unexpected lesions in the ovaries and tubes, which the tumour had masked. Or he may operate for disease of the appendages, and find in addition a small fibroid of the uterus.

The question arises: Is the myoma responsible, in any way, for the tubal or ovarian disease? I think, in many cases, it is. On the other hand, I see no evidence that diseased conditions of the ovaries and tubes can ever cause a myoma to develop in the uterus.

Heart Lesions.—It has been shown that myomata, especially those of large size and causing much hæmorrhage, exercise a very pernicious influence on the heart. The repeated hæmorrhages produce chronic anæmia; and, as a result, the heart is badly nourished. A large myoma causes mechanical obstruction to the circulation, and increased peripheral resistance. The result is that the heart muscle undergoes fatty degeneration and brown atrophy.

Degenerative Changes.—Myomata are peculiarly liable to various kinds of degeneration; indeed, I know of no other tumour so prone to secondary changes. They are found in about 20 per cent. of the cases. We may divide them conveniently into three great groups:—

(*a*) Non-malignant degenerations *without* necrosis; occurring in about 14 per cent. of myomata.

(*b*) Non-malignant degeneration *with* necrosis; occurring in about 4 per cent. of myomata.

(*c*) Malignant degenerations and complications; occurring in about 4 per cent. of myomata.

Let us consider each group in turn.

Non-Malignant Degenerations.—This group is a large one, and includes many different pathological processes. Amongst the mildest and most innocent are fatty degeneration, hyaline degeneration and calcareous infiltration. These are found in tumours which have ceased active growth, and may be looked upon as signs of their old age. They do not, as a rule, call for active interference.

But there are other degenerations characterised by marked activity and rapid growth of the tumour. These include acute lymphatic œdema, myxomatous softening, cystic degeneration, angiomatous changes, adenomatous growths, and the curious condition known as red degeneration.

There are certain clinical features common to nearly all these degenerations: (*a*) the tumour is usually, but not invariably, single; (*b*) after a period of quiescence it suddenly begins to grow rapidly, with increased pressure symptoms, and often severe pain; (*c*) the tumour changes in consistence, becomes more elastic and softer; in the cystic variety it fluctuates, and gives a thrill like an ovarian cyst; (*d*) in many cases it becomes more vascular, the enlarged arteries being felt pulsating in its walls, and a loud bruit being heard on auscultation. These changes may come on at any age, but are most common about the menopause. They may even come on years after the cessation of menstruation.

Amongst my 380 abdominal sections for myoma, I found non-malignant degeneration recorded in 19 cases (5 per cent.), of which no less than 13 were examples of cystic degeneration.

Red Degeneration.—Let me briefly call your attention to the curious condition known as red degeneration. It is sometimes called "hæmorrhagic degeneration." It is probably a form of acute aseptic necrosis, and hence is termed by some writers "red necrobiosis." In Noble's collection of 2,274 cases of myoma, it is recorded 13 times, or 1 in 175. Whenever it does occur it causes serious symptoms, and calls for immediate operation. Its essential cause is unknown. It is specially liable to occur in young pregnant women. The onset is sudden. There is acute pain, with vomiting, a rapid increase in the size of the tumour, and often some degree of fever.

Necrosis.—We now come to the cases where necrosis, or death of a fibroid, occurs. It happens in about 4 per cent. of all myomata. When a cystic fibroid undergoes necrosis, the fluid contents become converted into a kind of pus, and then the growth is termed a suppurating fibroid. It is rare for an interstitial myoma to necrose, probably because it is well supplied with blood on all sides. The submucous and polypoid varieties are, however, very prone to do so.

There are other modes by which a submucous myoma may become infected and necrose:—

(*a*) By the passage of a dirty sound in examining the uterus.

(*b*) By an intra-uterine operation, such as curetting, done with dirty hands or instruments.

(*c*) By the puncture of the growth with Apostoli's electrolytic needles. This was a fertile source of disaster when this method was in fashion.

However produced, when once necrosis has set in, it is unmistakable. The stench of these cases is sometimes appalling, filling the whole house. At the same time the patient becomes infected and poisoned by toxins absorbed from the gangrenous tumour; and, if not speedily relieved by operation, will die of septicæmia or pyæmia. In some of my most putrid cases, however, I have been amazed by the absence of any systematic infection, the patient being only distressed by the disgusting smell of her discharges. This, no doubt, must be explained by the slow onset of the process, allowing for self-immunisation.

These cases of sloughing fibroid may be mistaken for advanced cancer of the uterus—an error which would be disastrous if it led the surgeon to treat the case as hopeless, and not attempt to remove the growth. It is not always easy to differentiate without a thorough examination under an anæsthetic. If the cervix be softened and dilated by a tumour being forced through it, the tumour is a fibroid, and not a cancer. If, beyond the necrosing part, a smooth rounded mass can be felt, covered by mucous membrane, it is probably a fibroid. If the protruding part be brittle, and friable, and crumble under the finger, it is a cancer. A sloughing fibroid can be pulled away with forceps in stringy shreds or rounded masses; and, on close investigation of these fragments, some trace of the fibrous structure of a myoma may be seen. If still in doubt, a microscopic examination of a bit of *débris* will clear up the matter. It is of the utmost importance that a correct diagnosis be made, as an early operation will save the life of the patient if it be a fibroid. Indeed, I know of no cases which yield more brilliant results to timely surgical interference.

(a) Abstract of the Ingleby Lectures, delivered at the University of Birmingham, May 7th and 14th, 1908.

Malignant Degeneration.—The researches of modern pathologists and gynæcologists show that there is a marked tendency for a myoma to become directly transformed into a sarcoma. Winter examined microscopically 500 myomata, and found sarcomatous changes in 4 per cent. Martin found sarcomatous degeneration in 6 out of 205, Cullingworth in 1 out of 100, Schadlied in 6 out of 100, Haultain in 2 out of 120, Hirst in 3 out of 189, and McDowol in 20 out of 1,000 cases. In my own 380 abdominal sections for myoma, I found sarcomatous changes in 9 cases. Adding these cases together, we find it occurs in a little over 2 per cent. But this list includes only the sarcomata recognised as originating in myomata. Probably many other cases, thought to be primary sarcomata, have originated in unrecognised myomata. Hence I think that Winter's figures give the truer proportion—viz., 4 per cent.

Relation to Pregnancy.—Myomata tend to cause sterility. Mann found that 55 per cent. of married women with fibroids never conceived. Amongst married women generally only 15 per cent. are sterile, so there is nearly four times more sterility in myomatous women than in other women. It is fortunate it is so, as there can be no doubt that the occurrence of pregnancy adds greatly to the dangers of myoma. A woman with a fibroid is safer single than married, and a married woman with a fibroid is safer sterile than pregnant. Some authors, noting that myomatous women are often sterile, have suggested that sterility is a cause of myomata. They suppose that these women ardently long to have children, and that their unsatisfied maternal desires keep up a congested condition of the uterus, and, in some mysterious way, produce a myoma. I do not believe in transcendental pathology, and I think these theorists put the cart before the horse. The myoma causes the sterility, and not the sterility the myoma. It is, moreover, easy to understand how the presence of one or more fibroid nodules, embedded in the womb, may stimulate its sensory nerves, and awaken strong maternal passions.

Let us now consider the results of pregnancy in a myomatous uterus. Whilst some women, with moderately large fibroids, go through pregnancy and labour without a hitch, it is usually a serious complication. If the tumour be submucous or interstitial, the patient generally aborts about the fourth month; and this is the best thing that could happen to her. I have seen several cases of severe uncontrollable vomiting, in pregnant women with interstitial fibroids, due, I believe, to the inability of the uterus to expand with the growth of the pregnancy. In most of these cases abortion had to be artifically induced. When abortion occurs, whether spontaneously or induced, there is apt to be retention of placental tissue, and alarming hæmorrhage from imperfect contraction of the uterus. Another risk is that, following an abortion, a submucous myoma may necrose and be a source of sepsis. I have already referred to the special tendency of red degeneration to occur in pregnancy.

A fibroid may be so large that it may mechanically prevent the normal development of the pregnant uterus, and necessitate surgical interference. Some years ago, I had sent to me, by Dr. Davidson of Coventry, a patient with a huge myoma and also a five months' pregnancy. She was in great distress, and there was no room, apparently, for any further growth of the pregnancy. So I opened her abdomen and removed the entire uterus.

In some cases, the fibroid is impacted in the pelvis below the pregnancy in such a way that it is obvious the child cannot be born *per vias naturales.* Wherever situated, a large fibroid adds greatly to the risks of a full time labour. It may interfere with the contractions of the uterus, and so delay delivery. It may, by preventing contraction after delivery, cause retention of the placenta or alarming hæmorrhage. As a result of bruising or torsion, the growth may undergo necrosis, and cause fatal sepsis. It will thus be seen that the combination of pregnancy with a *large* myoma is a grave one, full of danger for the patient and anxiety for the medical attendant. The mortality is great, as in many cases surgical aid is not called in till it is too late.

Summary of Risks.—Let me now briefly summarise the risks a woman with a fibroid tumour runs :—

(1) More than half the cases suffer from severe hæmorrhage and chronic anæmia.

(2) Many cases develop heart disease, phlebitis, thrombosis and embolism.

(3) Others get retention of urine, cystitis, pyelitis, and hydro-nephrosis.

(4) In about one-third of the cases, the ovaries and tubes become diseased.

(5) In about one-fifth of the cases, some form of degeneration occurs, ending in nearly 5 per cent. in necrosis of the growth, 4 per cent. develop sarcoma, and another 4 per cent. cancer.

(6) More than half the patients are sterile; but, should pregnancy occur, the dangers increase with the progress of the gestation.

Natural cure of Fibroids.—There are three modes by which a "natural cure" of a myoma may take place :—

(1) A submucous fibroid may necrose and slough away; or it may be extruded through the cervix as a polypus, and drop off.

(2) A myoma may participate in the involution of the puerperium and disappear.

(3) It may undergo atrophy at the menopause.

The first mode—by necrosis and sloughing away of the tumour—I have already discussed. Needless to say its risks are much greater than those of the most formidable of the modern operations for fibroids. The gradual conversion of a submucous fibroid into a polypus, followed by its extrusion and separation *en masse*, does undoubtedly occur. But it is a long, tedious, and dangerous process, more likely to kill the patient than to cure her.

The second process of natural cure, viz.—by its sharing in the involution of the uterus after delivery—is also uncertain, and is more apparent than real. Myomata are very sensitive to changes in their blood supply. When pregnancy occurs, the increased vascularity of the womb causes the tumours to take on active growth. They often become more mobile—due no doubt to the softening of the surrounding uterine wall. An interstitial fibroid seems sometimes to be converted into a subserous one, by being pushed outwards toward the peritoneum by the growing ovum. Should the patient pull safely through the pregnancy and labour, the blood supply of the uterus rapidly diminishes. The tumour then shares in the process of involution, shrinks in size, and in some cases, seems to disappear. This fortunate result is, however, by no means a certainty; and in many cases the tumour, so far from shrinking, takes on more active development. It is probable, as Dakin says, that very few fibroids are absorbed; but many degenerate, become inflamed, or undergo necrosis. Only a few months ago I had to operate on a lady who had a large subserous fibroid growing from the top of her uterus. She had been confined three months before, when the tumour was discovered by her medical attendant (Dr. Peirce, of Langley). Instead of shrinking during the puerperium, it took on active growth. I opened her abdomen, and found a large cystic fibroid attached by a broad pedicle to the top of the fundus. I removed it by dividing the pedicle, saving the rest of the uterus.

Lastly, a natural cure may occur by the absorption and disappearance of a fibroid at the menopause. This phenomenon was at one time looked upon as almost a certainty. The woman was told that, if only she would wait till the change of life, the growth would disappear, and all her troubles would be at an end. But a sad experience shows that these hopes are illusory. As a matter of fact, the presence of a fibroid delays the natural change of life; and instead of the hæmorrhages ceasing at 45, they go on with increased vehemence until she is 50, 55, or even older.

Even if hæmorrhage ceases, this removes only one of the many risks of the condition. It is just at this period that the most serious forms of degeneration are apt to supervene. Noble, in his study of 4,880 cases, says he is not acquainted with a single authentic case in which a fibroid has entirely disappeared at or after the menopause.

Realising, on the one hand, the manifold dangers of myomata—the pressure symptoms, the cardiac and renal complications, the risks of degeneration, necrosis and malignant disease—and, on the other hand, the safety and the certainty of cure offered by modern surgical operation, I hold that we are not now justified in advising a patient with a troublesome fibroid to wait for the menopause.

THE PROMOTION OF UNIFORMITY IN THE REGISTRATION OF DISEASES IN HOSPITALS. (a)

By R. F. TOBIN,
Surgeon, St. Vincent's Hospital, Dublin.

GENTLEMEN,—"Order is Heaven's first law," and although it is possible to make out a case for disorder in certain relations—for instance, Herrick tells us that

> "A sweet disorder in the dress
> Kindles in clothes a wantonness,"

and that it creates

> "A winning wave deserving note
> In the tempestuous petticoat"

—still, I do not think that there is anyone in this audience who will have the hardihood to stand up and say a word for it in connection with registration of diseases. My object in speaking to-night is to suggest a simple means for forwarding what I have set forth in the title of this paper, and perhaps the best way I can introduce the subject is to tell you how I have been led up to the place where I now stand.

Some months ago the Board of Superintendence of Dublin Hospitals receiving Government grants, of which I am Secretary, decided that it would be well to amend the form on which the hospitals with which it is concerned send in a classified annual return of patients admitted, and I was directed to look into the matter. There was certainly necessity for the change, for the old form was quite obsolete—the classification being alphabetical, with the inclusive term abscess holding first place on the list. I shall not delay you by mentioning those with whom I have corresponded. Science does not recognise nationalities, and the list is therefore a long one; but I shall take this opportunity to thank all on that list for their letters and suggestions.

Anyone carrying out an inquiry such as I have been busy on will be struck, first, with what an excellent book is the "Nomenclature of Diseases of the Royal College of Physicians"; how far it is in advance of all other classifications; and then with how very little the profession generally know about it. My own ignorance of it was the first thing that was brought home to me, and then came the consolation of finding how widespread was my shortcoming. Of course, everyone knows that there is such a book; that it has a yellow cover, with a red linen back. But how many could lay their hands on it within five minutes? How many of us know the advances that have been made as new editions have come out? How many of us have studied it as we have the leads in a "no trump declaration"? My feelings towards the book are now those of a converted collier towards temperance. The care bestowed on its compilation, the eminence of the men who have worked at it, the difficulties as regards classification that have been overcome, the education that lies in an intimate acquaintance with it, are ever before me, as also is the fact that thousands of my brethren—of course, I except the learned men now listening—are still plunged in the ignorance that was mine until the other day. The means I suggest for spreading the light and for promoting uniformity in the registration of diseases in hospital is a very simple one. It consists in putting in every admission and discharge book alongside the column for the names of diseases a column for the numbers given to those diseases in the nomenclature, and in using, when the annual returns are being prepared, these numbers as a means of bringing together the various diseases in their proper order. This simple means of classification is in use in preparing the returns of the Army Medical Service, and it is found to work well. The numbers identify the words, and the necessity for looking out the number leads one to using the proper word. It banishes such terms as struma, scrofula, etc.

And here let me remark that, since my conversion, it has been a wonder to me why the Registrar-General does not give us a space for these numbers in the certificates of death, and ask us to fill them in.

In conclusion, may I point out that the addition of the number in each entry of a disease in the admission and discharge book, in place of giving increased trouble, has, as is always the case with what tends to order, a quite different result. In a very short time one comes to know the numbers of all the principal diseases, and so the initial trouble disappears, while thus advantage is permanent that from an admission and discharge book so filled up, any clerk can make out a classified return of diseases. Infective diseases, malignant diseases, diseases of the various systems that are not either infective or malignant, are compelled to fall into proper order, and a bracket to define the sections is all that is necessary to complete the return.

I now produce the front page of the form furnished to the hospitals under the superintendence of the D.H. Board, as it furnishes an illustration of how the system works. On it, as you perceive, the number of infective cases, of malignant cases, of injuries, etc., are seen at once.

A CLASSIFIED ANNUAL RETURN OF THE DISEASES OF PATIENTS.

TREATED IN..............................HOSPITAL DURING THE YEAR ENDED 19 .....

The following entries are made with a view to illustration.

No. in Nomenclature.	Disease.	No. Treated	No. Died	Class.	Totals of each class.	
					Treated	Died
13	Enteric Fever	6	1	Infective.	36	5
38	Scarlet Fever	4	2			
44	Tuberculosis, Lung	20	2			
44	" Knee-Joint ...	3				
44	" Abscess Tibia	1				
44	" Lupus	2				
50	Alcoholism	4	1	Intoxicants.	6	1
59	Plumbism	2				
79	Lipoma Circumscribed; Back	4		New Growths Non-Malignant.	5	
79	Papilloma, Villous, Vesical	1				
80	Sarcoma, Spindle-celled, Femur...	2	1	New Growths Malignant.	10	2
80	Sarcoma, Spindle-celled, Testicle	1				
80	Carcinoma, Scirrhus, Breast	4	1			
80	" Epithelioma, Lip	3				

As there are here to-night representatives of many hospitals, may I ask them to give this system their consideration, and if they approve it, to try and introduce it into the institutions with which they are connected. I have said it is in use in the Army Medical Service, and it may be in more general employment than I am aware of. If so, so much the better. It is for its universal adoption that I raise my voice to-night. Why should not each disease carry a like number in every land? This, I believe, will come. Let Ireland lead the way towards such a consummation, and let there be at least this one point of Union between her sons.

(a) Paper read before the Section of State Medicine, Royal Academy of Medicine in Ireland, May 1st, 1908.

THE SUPPORTS OF THE FEMALE PELVIC VISCERA. (a)

By RICHARD H. PARAMORE, M.D.LOND., F.R.C.S.,

Clinical Assistant, Department for Diseases of Women, St. Bartholomew's Hospital.

THE author introduced his paper by saying that the supports of the pelvic viscera could not be discovered by anatomical research alone, but that it was necessary to conjointly investigate the actual living processes which occur in the body. The pelvic cavity was shut in below by the levator ani muscle, the coccyx muscles, and their connective tissue attachments. This muscular sheet, called the pelvic floor, limited the abdomino-pelvic cavity inferiorly; and in uniformity with the other limiting musculation of the body cavity, it was clothed by a layer of subperitoneal tissue, and was lined by peritoneum. Within this subperitoneal tissue the pelvic viscera were embedded; and these protruded into the cœlomic cavity and elevated the peritoneum from off the pelvic floor. Besides viscera, this layer contained the blood and the lymph vessels, the lymphatic glands and the nerves and the ureters. In places it was composed of soft loose cellular tissue, containing more or less fat; in other parts the tissue had become condensed to form ligamentous strands which contained unstriped muscle fibres, and which were especially related to the pelvic blood vessels, and, therefore, had been styled the perivascular connective tissue sheaths. Owing to their strength and to the fact that they were attached to the bone, it had been supposed they constituted the chief and the only supports of the viscera.

The speaker then showed the similarity between the condensations of the pelvic visceral connective tissue and the condensations which occurred in other parts of the cœlomic cavity, and especially in connection with the duodenum (suspensory muscle, &c.). He did not, however, believe that this ligament suspended the duodenum, which he thought was supported by the viscera below it, and which in turn were kept in place by the tonic contractions of the belly-wall musculature; but he considered this ligament merely served to anchor the duodenum to the spine and thus prevented too great excursions of it.

He said there was no essential difference between the condensations of the subperitoneal tissue in one place and that in another, and thought the visceral ligaments of the pelvis did not normally support the uterus, although on glancing at the pelvis it might appear that they did so. A comparison, however, of the visceral connective tissue apparatus with the pelvic diaphragm placed beneath, showed that whilst the pelvic diaphragm, on account of its striated muscle, was a highly elastic obturator, the visceral connective tissue was little if at all elastic. It was this lack of elasticity, the impossibility of yielding to excessive pressure from above without stretching, and the equal impossibility of returning to a previous position after such stretching, that made it impossible for the visceral connective tissue sheaths to play the part of a support adaptable to all the requirements of the pelvis.

He considered these ligaments to function during the act of defæcation, and that the pelvic floor descended during this act they undoubtedly prevented a too great descent of the uterus.

Dr. Paramore said the pelvic floor was to be considered identical in structure and in function with the anterior abdominal wall. The fact that the abdominal and pelvic cavities were, indeed, one cavity indicated, that they were enclosed by a universal means, similar alike in anatomical structure as in physiological function; nor should the presence of the genito-urinary rectal passages, complications as they were, be sufficient to blind them to the essential similarity between the two parts. These in the living body acted as antagonists to each other, in that increase of contraction of the one reflexly caused increase of contraction of the other. The outcome of the simultaneous contraction of these two groups of muscles, in the superior one of which the thoracic diaphragm must, of course, be included, was the intra-abdominal pressure.

This pressure acted by thrusting the pelvic viscera still further downwards upon the pelvic floor; and in the presence of this down thrust the viscera were maintained in their position by the levator ani muscle. The proof that this was so was shown by the invariable occurrence of prolapse when this muscle had been sufficiently injured, and the intra-abdominal pressure periodically became sufficiently high; and, as Halbam and Tandler had pointed out, was exhibited in the most beautiful way in cases of congenital paralysis of the muscle in association with spina bifida.

CLINICAL RECORDS.

CORNUAL GESTATION IN ONE HORN OF A BICORNUATE UTERUS—RUPTURE—RECOVERY. (a)

BY J. B. HELLIER, M.D.LOND.,

Lecturer on Gynæcology, University of Leeds, &c.

THE patient, æt. 33, enjoyed good health previously. Her first pregnancy terminated in normal labour, April, 1907. She ceased to menstruate in the following November, and was perfectly well until March 15th, 1908, when about 12 p.m. she received a violent blow on the lower part of the abdomen on the right side. Either she was directly kicked in this region, or was driven against a sharp corner. She felt faint at once, and was unable to lie down properly on account of vague abdominal pain. She became seriously ill next day, and on March 17th required catheterisation, and was admitted into the Leeds Infirmary. The lower half of the abdomen was full and tender, respiratory movements in this situation were defective, and there was some dulness in the right flank. The pulse was weak and rapid. The usual signs of pregnancy were present. It was considered that the case was one of internal hæmorrhage, and that either the uterus was ruptured, or some vessel in the pelvis. There was no vaginal bleeding.

Abdominal section was performed the same day, and a four months' fœtus, enveloped in the amnion lay superficially as soon as a median incision was made. A very large quantity of blood clot was in the abdomen and pelvis. The sac lay on the right side and looked very much like a matured uterus with retracted walls, the placenta having escaped into the abdomen, but retaining a slight attachment to the interior of the sac. On the left side of the sac there was a uterus of normal size, to which it was attached by a thin fleshy pedicle about 2¼ inches broad and ¼-½ inch thick. This was ligatured and divided, the ovarian artery being separately secured. The abdomen was cleared of clot, and closed without drainage. The pulse varied from 144 to 156 immediately after the operation, and the temperature rose to 101° on the second night. After this the patient made an uninterrupted recovery, and was discharged quite well on April 11th. On examination of the specimen, which was also shown, the sac-wall appeared to consist of muscular fibres exactly like the uterine muscle, and this was confirmed microscopically. The Fallopian tube was attached on the distal side of the sac. The uterine end of the round ligament was attached in front of and slightly below the tube.

(a) Abstract of Paper read before the Royal Society of Medicine (Obstetrical and Gynæcological Section), May 14th, 1908. For discussion see page 584.

(a) A Note read before the North of England Obstetrical and Gynæcological Society, May 15th, 1908.

The cornu did not communicate with the cavity in the left side of the uterus. It was a curious coincidence that the blow, which certainly caused her symptoms, should have fallen the gestation side, and if the patient had succumbed to the injury, an interesting medico-legal question would have been raised, which might have been compared to cases where blows on the chest have ruptured aneurysms.

OUT-PATIENT'S ROOM.

KING'S COLLEGE HOSPITAL.

Old Potts' Fracture.

By PEYTON BEALE, F.R.C.S.

Amongst the out-patients was a man, æt. about 40, complaining of very marked flat foot. He had suffered from a fracture of the lower end of the fibula about two years previously, and it had been treated at the time with a back and side splints, being subsequently put up in plaster. The present condition showed that the broken ends of the fibula had united forming an obtuse angle outwards, thus causing the typical displacement of the foot. The case had probably been one of Potts' fracture with rupture of the internal lateral ligament of the ankle. Mr. Beale said that he had for long advocated in these cases when it was thought advisable to use a back splint that the footpiece of the splint should be set on the slant in such a way that the foot was kept at right angles to the leg, but at the same time markedly *inverted*. He considered the best splint for cases of Potts' fracture was undoubtedly Dupuytren's, as this, if properly applied, necessitated the foot being strongly *inverted*. In his experience most of the troubles which occurred after fractures of the tibia and fibula were due to neglect of the precaution of putting up the foot in a markedly inverted position. In the present case he suggested that the patient should be admitted to hospital, and the fibula divided close to the seat of the original fracture, the ends would then be levered outwards, the foot at the same time being forcibly inverted, thus leaving a gap between the ends of the fibula. A Dupuytren's splint would be applied for the first fortnight, and then the foot and leg would be put up in plaster, the foot being markedly inverted.

Double Parotid Tumour.

A woman, æt. about 35, complained of an enlargement in front of and below both ears. She stated that she had noticed it first on the right side three years ago, that it was painful, particularly on moving the lower jaw. Shortly afterwards she noticed the swelling on the left side, and both had steadily increased up to the present time. Occasionally, and particularly at menstrual periods there was considerable pain in the parotid region. It was quite obvious that the swellings were enlargements of the parotid glands. At the time the patient presented herself both were rather tender, as her menstrual period was just beginning. The tumours felt hard and adherent to deeper parts, but there was no evidence of enlargement of lymphatic glands or of any cachexia, so it was supposed that the tumours were in all probability myxo-chondromatous. It was suggested that the patient should be admitted and carefully watched, the abdomen being examined in order to ascertain whether there was any enlargement or disease of the ovaries, tubes or uterus. It was fairly common, Mr. Beale pointed out, to find a parotitis in association with ovarian or testicular disease; such parotitis was as a rule subacute to commence with, but might persist in a chronic form for many months, and was sometimes exceedingly difficult to diagnose from a chondroma. Many of the chondromata of the parotid when removed were found to be in part at any rate endotheliomata. He imagined that they started as connective tissue tumours, and developed endotheliomatous characters later on.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Obstetrical and Gynæcological Section.

Meeting held May 14th, 1908.

The President, Dr. Herbert Spencer, in the Chair.

Dr. R. H. Paramore read a paper on the

SUPPORTS OF THE FEMALE PELVIC VISCERA,

in which he contended that the supports of the pelvic viscera could not be discovered by anatomical research alone, but that it was necessary to conjointly investigate with the actual living processes. A full abstract of the paper will be found on page 583. In the discussion that followed,

Professor **Paterson** (Liverpool) submitted that a great deal of sound anatomical work had been done in recent years in regard to the mechanical supports of the pelvic viscera. With regard to the means of support of the pelvic viscera, he was inclined to lay little stress on the so-called "intra-abdominal pressure," nor did he ascribe great importance to the power of the pelvic ducts, vessels, and peri-vascular, connective tissue to maintain the viscera in position. There were, however, two series of structures essentially responsible for the maintenance of normal conditions within the pelvic cavity. The structures comprising the pelvic floor formed, in his opinion, the chief factors in supporting the viscera—the symphysis pubis, triangular ligaments and compressor urethræ, perineal body, levatores ani and external sphincters, and the ano-coccygeal body. Any laceration or weakening of these structures would predispose to prolapse of the superimposed viscera. The rectal ampulla, when distended by fæces, is capable of serving as a support for the vagina and uterus. It is the genito-urinary passages—prostatic urethra or vagina and urethra—that are bound down to the pelvic walls and floor in their course to the perinæum. This is effected by means of a special investment of the pelvic fascia (suspensory ligament of the vagina and urethra), which, springing from the sides of the pelvis in the neighbourhood of the ischial spine as a well-defined sickle-shaped fold sweeps inwards to envelop the urethra and vagina, leaving a clear portion of the pelvic cavity behind for the passage of the rectum. This fold of pelvic fascia is very vascular. It separates into two layers, of which one sweeps across the middle line (recto-vaginal layer), and, separating the vagina from the rectum, is attached below to the perineal body. The upper layer has an attachment to the white line, and becomes the lateral true ligament of the bladder. Below the bladder in front it becomes the anterior true ligament of the bladder on each side, and gains attachment to the symphysis pubis. The ligamentum transversale colli of Mackenrodt is probably represented by the free edge of this band of pelvic fascia, which gains attachment to the lateral fornix of the vagina.

Mr. **Arthur Keith** said that his investigations led him to infer that prolapse, partial or complete, of the pelvic viscera is primarily prevented by the action of the musculature of the pelvic floor. It is necessary to distinguish two distinct problems:—(1) The manner in which the uterus is maintained in its normal relationship to the pelvic floor; and (2) the manner in which the uterus is maintained in its normal relationship to the pelvic viscera. It is with the first of these problems with which we are chiefly concerned. At the present time three structures are regarded as normal uterine supports:—(1) The musculature of the pelvic floor; (2) the visceral ligament of the pelvic fascia; (3) the strong perivascular and perineural sheaths which surround the pelvic vessels and nerves. It is not to the perineural and perivascular fibrous supports that the primary duty of supporting the uterus can be ascribed. They serve primarily to safeguard the blood and nerve supply of the uterus. The manner in which a Hodge's pessary supports a uterus which tends to become prolapsed is simply by expanding and keeping expanded and rigid the vagina, whereby the damaged levatores ani which can get no purchase on a flaccid vagina can obtain a hold on and keep up a rigid vagina.

Dr. W. E. **Fothergill** (Manchester) adhered to the views he had previously expressed as to the supports of the pelvic viscera. It required but a slight mental effort to imagine a woman with a perfect levator ani and perinæum, in whom the uterus, vagina and bladder had been completely freed from their attachments and lay loose within the pelvis resting upon the upper surface of the pelvic diaphragm. Did anyone suppose that the organs would remain there for long? The pelvic diaphragm and the sphincter layer of muscles could not prevent the escape of the fœtus or of a mass of fæces. Why should it be supposed that they prevent the escape of the plastic mass formed by the uterus, vagina and bladder? It was obvious that these organs were normally supported by the connective tissue intervening between them and the sides of the pelvis, and the important portion of this connective tissue was that forming the perivascular sheaths.

Dr. **Hastings Tweedy** (Dublin) said that the author had furnished them with anatomical data which clearly showed that strong ligaments crossed the lateral fornices and formed, in Dr. Ovenden's words, "easily defined and striking objects": that they were of themselves capable of supporting the uterus in a normal position; that when they were severed the cervix sagged downward, and this in spite of the fact that all the other uterine ligaments were uninjured. There is convincing proof that these ligaments, when acting normally, keep the cervix tucked upwards and backwards, and when performing this function they are subjected to no greater strain than those which affect other similar structures; as, for instance, liver ligaments. The levator ani muscle is essentially the muscle which keeps the vagina from deformity, and, offering a counter-force to the intra-abdominal pressure, it enables the anteflexed uterus to lie between these forces with little aid from its ligaments. If, however, the cervix descends it is powerless to maintain the uterus in anteflexion, nor can it do so if the uterus has once fallen into retroflexion. A tear in the pubo-coccygeal fibres will inevitably result in the occurrence of cystocele and rectocele, with slow descent of the cervix. He had never seen a procidentia due to childbirth in which the cervix was not torn. His operative experience furnished him with further evidence as to the importance of these ligaments.

Dr. **Briggs** (Liverpool) held, on both anatomical and clinical evidence, that the pelvic viscera were supported by (*a*) the levatores ani, (*b*) their dense lateral pelvic fasciæ, (*c*) the perivascular and other loose cellular tissue. The integrity of the pelvic supports, like the integrity of a joint, did not depend upon ligaments. Fascial structures were purely passive and were maintained or restored by their muscles. The widening of the linea alba during the later months of pregnancy was corrected in vigorous women after labour by the tonicity and subsequent re-approximation of the muscular recti abdominales. Similarly in planning operations in suitable cases of uterine prolapse, Dr. Briggs believed the restoration of the levatores ani and their fasciæ by extensive buried sutures in, under and around the vaginal walls without the removal of any tissues, was still to remain the main aim of the surgeon. The operative treatment of prolapsus uteri rests upon the restoration of the muscular and fascial strata.

Dr. **Alexander Macphail** (Glasgow) remarked that the full and complete contributions of other anatomists to the discussion had left very little of practical value to be added from that point of view. He would emphasise, however, the distinct attachment of the levator ani to the vaginal wall close to the cervix, and the close connection established there with the visceral layer of the pelvic fascia, the latter probably being the more important in the matter of uterine support. It appeared to him that in the course of the discussion a tendency had been shown to wrongfully assign a supporting function to one set of structures to the exclusion of others. The *via media* of attributing this both to the "suspensory fascia" and to the "pelvic diaphragm" seemed to him to be the only sound course from the anatomical point of view. As to the priority of the lesion in these structures in the incidence of prolapse, he had nothing to add from personal observation, nor had he been able to gather a definite conclusion from the experience of others; but it seemed to him that nothing short of the testimony of a watchman in the parametrium at the moment of its occurrence would justify dogmatic statements on the point.

Dr. **Macnaughton-Jones** still believed that there was a combination of forces at work in the pelvis in resisting any downward pressure on the uterus and maintaining it in its normal relation to the other viscera. The chief of these, no doubt, were the pelvic fascia and the levator ani. It was universally acknowledged that the suspension structures in the vault of the pelvis had but little power to prevent prolapse. Still, they played a certain part, and clinical experience, as well as the results of operations on those suspensory structures proved this.

Dr. W. S. A. **Griffith's** view of the levator ani was that it is an auxiliary means for the support of the pelvic organs put into action to resist special strains, while the general pelvic fascia which forms a continuous sheet varying in density in certain positions was the chief support against ordinary conditions of pressure. The injuries produced by childbirth were the great determining cause of prolapse.

Dr. **Inglis Parsons** could not agree that the uterus was maintained in its position by the intra-abdominal pressure with or without the pelvic floor. The other chief factor, according to Dr. Paramore, in holding up the uterus was the pelvic floor. How did he account for those cases where the pelvic floor was ruptured completely, and yet the uterus did not come down? Further than this, complete procidentia sometimes occurred in virgins with an intact pelvic floor. Prolapse did sometimes follow rupture of the perinæum and sometimes did not. The only explanation of this phenomenon was that the ligaments in some women are strong enough to keep up the uterus without assistance, whereas in other cases the ligaments were weaker and could not stand alone, but required the help of the pelvic floor. Without being an egoist, he might point the results of his own operation of injecting the broad ligaments so as to increase the strength of the pelvic band. This operation demonstrated that the uterus could be kept up by even one ligament if it were strong enough. At the same time repair of the pelvic floor did undoubtedly help matters, but was not necessary to success in all cases. In conclusion, he would say:—(1) That the chief factor in supporting the uterus is the connective tissue with elastic and muscular fibres passing from the uterus in various directions to the walls of the pelvis, first described by Savage. (2) That the pelvic floor also helps indirectly to keep up the uterus by preventing prolapse of the vagina. (3) That intra-abdominal pressure does not keep up the uterus, but is the chief factor in causing prolapse.

The **President** (Dr. Herbert Spencer) said that the Section was indebted to the author for his valuable *résumé* of the views held on the supports of the uterus and to the distinguished anatomists who had taken part in the discussion, and who had taken a wider view of the matter than that of Dr. Fothergill at a previous meeting. The truth appeared to be that the supports of the uterus were of a composite character, including atmospheric pressure, muscles, ligaments and fascia. Some confusion, he thought, arose from speaking of the uterus being supported by intra-abdominal pressure; it was rather extra-abdominal or atmospheric pressure, the retentive power of the abdomen of Matthews Duncan. He was rather surprised to hear that the cardinal ligament of Mackenrodt was inserted only into the vagina. His own operative experience led him to believe that it was inserted into the cervix.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

Meeting held Friday, May 1st, 1908.

The President, Dr. W. R. Dawson, in the Chair.

A PLEA FOR UNIFORMITY IN THE REGISTRATION OF DISEASES IN HOSPITALS.

Mr. Tobin read a short paper on the above subject, said that his object was to suggest a simple means for forwarding what he had set forth in the title of his paper. He enlarged on the excellence of the nomenclature of disease of the Royal College of Physicians, London, and on the small acquaintance with it shown by the bulk of the profession. He proposed as a means for promoting uniformity the putting, in every admission and discharge book, alongside the column for the names of diseases, a column for the numbers given to these diseases, in the nomenclature of disease, and in using, when annual returns were being prepared, these numbers as a means of bringing together the various diseases in their proper order. He handed round forms showing how the system worked. Mr. Tobin's paper will be found on page 582.

Dr. **Kirkpatrick** said the important thing about a classification was that it should be a general one, enabling them to compare the returns of one hospital with another. Under present arrangements such a thing was impossible. Objection might be taken to the classification in the nomenclature of disease. The Royal Army Medical Corps were compelled to make their returns in accordance with the nomenclature, and if a disease were returned which was not in it, the return was sent back to be made out according to the books. This he had heard complained against, as some diseases were not mentioned in the nomenclature, while others were put down under more or less obsolete names. The method, however, was one that could be universally adopted. The difficulty would occur not so much with hospital registrars as with the terms in which the diagnosis would be put down when the patient was discharged. Different names would be used in the diagnosis of the same disease, and there were diseases which were not easy to put in any class. Besides, it was impossible to expect that hospital physicians and surgeons, when diagnosing, to turn up the book to find a number. They would enter the name of the disease, and leave the classifying to the registrar, and difficulty would arise with omissions or differences in the nomenclature. It seemed to him a great pity that, while they had in Dublin a number of hospitals—none with large numbers of beds, but the aggregate considerable —they had no hospital statistics of any great value from the Dublin school. He heartily welcomed Mr. Tobin's suggestion, though he thought his plan would require some modification which might be brought about by a meeting of the Registrars of Hospitals.

Dr. J. **Magee Finny**, speaking as a member of the Board of Superintendence of the Dublin Hospitals, corroborated Mr. Tobin's account of the difficulties they had in getting uniformity in the returns for their annual report. The Board was unanimously in favour of some such step, and although there was room for improvement in the scheme—such as columns for cancerous and tubercular disease, and for the different fevers—the more one thought of it, the more one saw the necessity for adopting some such plan, and he hoped it would extend beyond Ireland.

Dr. **Little** thought the scheme would do as much as any scheme could to get over the inherent difficulties of the subject. They would get cases in which a lesion was clear, but more often in hospitals they would find a patient suffering from a combination of diseases which would require classification under several headings. A vague term might be accurate, and a precise term erroneous.

Dr. **Drury** pointed out the difficulty of registering, according to the nomenclature, in the case of Bilharzia, an example taken at random, which, registered under the scheme proposed, would come under a quite erroneous heading.

Dr. **O'Farrell** instanced the difficulty he had met with in trying to get registration done by the nomenclature, not only as regards classification, but also as to obtaining right diagnosis, previous to his adopting, as Registrar of St. Vincent's Hospital, the plan proposed by Surgeon Tobin.

The **President** said it was clearly impossible to adopt any final system of classification which would be universally agreed to. All that could at present be done was to adopt a working system that would enable statistics to be compared. He could personally appreciate the great advantage of uniform classification. At present they had to squeeze round diseases into square holes, but such was unavoidable in their present state of knowledge, and probably would be for centuries to come. Any system which could be universally adopted would produce better results than the haphazard classifications which had been in vogue.

Mr. **Tobin**, in reply, said the inconsistency shown by Dr. Drury was exceptional. He had not once come across a similar case in his work with the returns. If the subject had been taken up in the past the book would not now be deficient. The difficulty of classification was due to the shortcomings of their pathology. He trusted it would be possible to bring the Registrars of hospitals together to talk the matter over. If they could all work together they would have continuous improvement, and would soon find out the points in which the nomenclature failed.

VITAL STATISTICS OF THE OLD MEN'S ASYLUM.

Dr. **Ledwich** read a paper on the above, in which he stated that during the twenty years he had been physician to the Institution ninety-eight old gentlemen had been under his care. Of these seventy-one had died, twenty-two are still living, and five had resigned. Of the total number who died, five lived to be over ninety years of age, and one to be over one hundred. The records of death only deal with sixty-five cases, because in six cases the notes have been lost. In these sixty-five cases senile degenerations account for 24.6 per cent. of the deaths, while lung diseases are responsible for 15.3 per cent., and apoplexy for 9.2 per cent., an interesting feature of the statistics being that there were only three cases of malignant disease and four cases of enlarged prostate. Another feature of interest was that in the summer of 1891 there occurred an epidemic of contagious skin disease resembling pityriasis rubra; eight of the inmates and three female servants were attacked. He remarked that a similar epidemic took place at the same time in London at the Paddington and Marylebone Infirmaries in December, 1891. He then referred to longevity, and showed an interesting table in which he had recorded the ages, ages of parents, and, where possible, of the grandparents of thirty-seven of the old gentlemen. This table also showed their past habits as to alcohol, tobacco and exercise, and the state of their hearts and blood vessels. On studying the table, Dr. Ledwich said that he was forced to the conclusion that heredity had more to do with longevity than had habits, as nearly all of the men who had lived to a great age could show longevous parents, while many of them had been addicted to the use of alcohol and tobacco in immoderate quantities.

Dr. **Drury** said the statistics were most interesting, as being the result of accurate observation of a clearly defined class, who had lived their lives under somewhat similar conditions as to work and environment.

Dr. **Kirkpatrick** inquired as to whether Dr. Ledwich had found signs to any great extent of atheroma of the arteries, and whether inmates having such a condition died soon. They had been accustomed to regard syphilis as one disease of youth which was most likely to shorten life, and he was, therefore, extremely interested to hear that over 18 per cent. of the inmates had a history of syphilis. Was this history verified by scars? It was also remarkable that so few had died of malignant disease, a fact which was of very considerable importance in view of statements which had been made as to the increase of malignant disease in the country. They had been taught that malignant disease was essentially a disease of the latter half of life; but the majority of patients whom they now saw with malignant disease were probably under fifty.

Dr. **Matson** was anxious to know something of the diet of the patients. He had himself tried to follow out a scheme of diet in a similar institution, but had to give it up, and allow the patients what they liked. His own observations in regard to alcohol and heredity were much the same as Dr. Ledwich's.

Dr. **Ledwich**, in reply, said he would add the statistics regarding the blood vessels to his table. He had great difficulty in obtaining information about syphilis, and had not examined for scars. The inmates got meat once a day. Alcohol was stopped on admission to the asylum, and he had never found any harm from the sudden stoppage.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The President, Dr. **James Ritchie**, in the Chair

A CLINICAL meeting, illustrative of the subject of
DERMATOLOGY,
was held in the Royal Infirmary on May 20th, 1908.

Dr. **Norman Walker** gave a *résumé* of the work of the Skin Department of the Infirmary for the last 16 months, with special reference to groups of interesting cases and to those subjects at present attracting attention. He prefaced his remarks by saying that he had recently adopted the system of card indexing all the cases, and that in this way statistical inquiries were facilitated. In Edinburgh, however, where skin cases underwent a process of sifting at various dispensaries before they came to the Infirmary, he thought that in the latter institution there must therefore be an undue proportion of the rarer forms of skin disease. Taking up the diseases to which he wished particularly to call attention, he first alluded to alopecia areata. It appeared to be about twice as frequent relatively to the total number of patients seen as in either London or Glasgow. Without pressing the argument, he thought that this supported the view (which he held) that the disease was infectious. Favus was next referred to. It was notoriously common in Edinburgh, but he doubted whether many of his audience realised that he could have, had he wished, collected 60 cases to show. He spoke strongly of the serious state of things this represented. In private practice, as was well known, favus could be cured readily enough. Among the poor, however, it was frequently incurable. The reason for this was simply that the patients would not, and that there existed no means of compelling them to, attend regularly. In consequence these children suffered from a disfiguring malady, their education was utterly neglected, and their future careers blighted. If means could be found to enforce the attendance of such children until a cure was effected, favus could easily be stamped out. Impetigo contagiosa showed a definite epidemicity among the cases. In some months (not the same each year) the disease was much more common than in others. Herpes zoster also showed a similar incidence. Lupus erythematosus was held by many authorities, particularly in France, to be tuberculous in origin. It was not alleged that the lesion was due to a local tuberculosis, but that it was caused by the toxins of tubercle bacillus located in a distant focus. Certain post-mortem examinations had cast doubt on this, and Dr. Walker had investigated the point by the use of Pirquet's cutaneous reaction. He had only one positive result among several cases of the disease. This he thought was strongly against the idea that it was tuberculous. He protested against the indiscriminate use of the Calmette reaction, as one patient on whom he had tried it had almost lost the sight of one eye. Speaking of lupus vulgaris, he thought that not the least of the benefits of the introduction of the X-ray and light treatment was that from them we had learned the importance of patient, prolonged, and persevering treatment. He showed a number of cases which were practically cured as the result of years of treatment. The London Hospital lamp had been tried, but was not very serviceable. He regarded the persevering application of oleate of mercury as occupying nearly as high a place in the therapeutics of lupus as the X-rays themselves. He had been struck by the number of times he had observed epithelioma develop in the course of the X-ray treatment of the disease. Several cases were shown illustrative of this. Excision had been employed in one case affecting the face, but there had been extensive recurrence. In other cases he had obtained a cure by scraping and the application of caustics. Potassa fusa, arsenious paste, and chromic acid were the caustics used. The second was undoubtedly highly efficient, its disadvantage being that it was extremely painful, which prevented its application being continued. Patients required to be kept under morphia when it was used. Whatever the relation of the cancer to the X-rays was, he thought it ought to be looked out for, and though it did not necessarily mean that the rays must be discontinued, it certainly was wrong, in his opinion, to say that if epithelioma developed, larger doses of the rays were indicated. Molluscum contagiosum was not a very common disease in his series. He had noted, however, among the cases a group of five patients who had all been in the habit of frequenting the same public bath. Acne rosaceæ was commonly ascribed to digestive disorder; he was able to say that this was relatively rare in his cases. He showed a patient suffering from the disease associated with seborrhœa, and he believed that there was a connection between the two disorders. With regard to ringworm, they had not found that the X-ray treatment gave such precise results as in Paris. Cases of ringworm of the nails were shown, and it was remarked upon as worthy of note that, although in some of these the disease had lasted for months, and although the organism was the large spored trichophyton (the same which causes tinea circinata), no instance of infection of the skin from the nails had been met with. Turning, in conclusion, to the general question of vaccine therapy, Dr. Walker showed a severe case of sycosis which had been quickly cured by vaccinations with his own staphylococci. In lupus, if tuberculin were to be of any practical use it must be given in some way which did not necessitate the estimation of the opsonic index. His practice was to give 1-1,500 mg. of tuberculin every fourth week, and he was satisfied with it as an adjuvant to local treatment. Dr. Walker also showed a case of actinomycosis cured by large doses of iodide.

Dr. **Gardiner** showed a somewhat unusual case of erythema multiforme, which in some respects resembled a dry eruption; (2) a patient after a recurrence of ringworm of the scalp. In the first attack the small spored fungus, on this the large spored fungus, had been found.

Dr. **Cranston Low** showed a patient who now suffered from pemphigus foliaceous, and who had previously been under treatment for dermatitis herpetiforme. Such a sequence of events had been described in other instances, and whether the condition be named as dermatitis herpetiforme or pemphigus foliaceous, it was a well-defined clinical entity. The patient was receiving vaccines of an organism cultivated from the vesicles. He also showed a commencing case of actinomycosis fungoides.

Dr. Low showed (for Mr. Miles) a patient with unusually well marked rupia.

Dr. J. S. Fowler showed an infant suffering from urticaria pigmentosa. The case was quite characteristic: the eruption dated from the sixth week, and was distributed all over the trunk and limbs. Factitious urticaria could be readily produced, and when the eruption was irritated the pigmented spots took on temporarily the appearance of wheals. Histologically the essential feature of the lesion was a deposit of mast cells.

Mr. Wade showed specimens of hyperkeratosis plantaris and of mycetoma.

A demonstration of casts, photographs, etc., was also given in connection with the meeting.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held Friday, May 8th, 1908.

Dr. William Ewart in the Chair.

The Chairman read a paper on the "empty bronchus" treatment by posture in the bronchiectasis of children. His paper was devoted mainly to the management in children of the postural and respiratory aspects of the treatment, which was likely to be successful in proportion to its early adoption. He said that continuity of treatment was essential. The bronchus must be kept empty and the lung must be kept active for a nocturnal as well as diurnal treatment. The costo-abdominal elastic belts worn continuously stimulated the thoracic respiratory mechanism as well as abdominal. In the continuous postural method introduced by him, the declining of the bronchial and tracheal outlet was provided by the inclination of the bed during the night and during intervals of resting in the day.

Dr. Philip G. Lee (Cork) reported the following case for diagnosis:—The patient was a strong and healthy child of two years and six months. Four weeks previously she had marked wry neck, but otherwise was perfectly well. A week later she had extreme retraction of the neck. While on her way to see him she fell, and when he saw her both legs were paralysed. Four days later she had three convulsions, and the retraction of the neck completely disappeared. Subsequently the calf muscles wasted with the reaction of degeneration. There was no paralysis of the bladder or rectum. The peculiar features of the case were the nature of the onset, and the entire absence of fever and malaise.

Dr. O. K. Williamson showed a case of aortic and mitral stenosis.

Mr. Hugh Lett showed:—(1) A case of supernumerary digits on hands and feet in a baby, two months old. A similar condition was exhibited in the mother and a brother of the patient. (2) A girl, æt. 10, with forward dislocation of the inner end of the clavicle. (3) A case of multiple ecchondroses in a boy, æt. 9. The ecchondroses were extremely numerous, and were present not only on the long bones, but on the scapulæ, ribs and skull. (4) A child, aged 15 months, with hydrocephalus, genu recurvatum, and talipes valgus.

Dr. Porter Parkinson showed a case of abdominal tumour.

Mr. Russell Howard showed specimens of:—(1) Achondroplasia; (2) An anencephalic fœtus; (3) Intra-uterine amputations.

For the week ending May 16th there was not one death registered for the whole district of Penge and Anerley, which has a population of 23,918.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held Friday, May 15th, 1908.

The President, Dr. A. J. Wallace (Liverpool) in the Chair.

Mr. R. Favell (Sheffield) exhibited a specimen of fibroma of the ovary successfully removed by abdominal section from a patient, æt. 25, who had complained of abdominal pain for three years. Menstruation was regular, of the 28-day type, and lasted 3 days. The tumour was of the diffuse variety, undergoing cystic degeneration, and microscopically proved to be a pure fibroma. There was no ascites. Mr. Favell also recorded a case of Cæsarean section performed on account of labour obstructed by ovarian cyst. The patient was vi-para, æt. 39, previous labours having been normal. Labour pains commenced at 9.30 a.m. on January 9th, and the membranes ruptured at 5.30 the same evening. She was admitted to hospital at 11.30 p.m. As the pains were so frequent and severe it was decided to perform Cæsarean section, together with the removal of the tumour, rather than vaginal ovariotomy. This was accordingly done, and recovery was uneventful.

Dr. Hellier (Leeds) related a case of cornual gestation in one horn of a bicornuate uterus, in which rupture was attributable to a blow. (This will be found on page 583 of our present issue.)

Dr. Lloyd Roberts (Manchester) communicated a case and showed the specimen of epithelioma of the left labium majus, recurring in a woman, æt. 45, eighteen months after the removal of the clitoris and right labium majus for a similar growth. Complete relief followed for twelve months, when a painful nodule appeared on the left side. It did not seem to be a direct extension from the original growth, as healthy tissue intervened between it and the scar. No glandular infection was found. The growth was widely excised. The chief feature of interest lay in the possibility of the second growth being due to direct contact and infection from that in the right labium.

Dr. Croft (Leeds) mentioned a case of Dr. Walter Thompson's of the pyelo-nephritis of pregnancy in a primiparous patient, æt. 26. Persistent vomiting, abdominal pain and pyuria, with severe febrile disturbance, were present, and it was deemed advisable to terminate the pregnancy at the sixth month. The membranes were punctured, and, following the delivery, all the symptoms subsided, and the pyuria was gradually disappearing.

CENTRAL MIDWIVES BOARD.

Meeting held Thursday, May 21st, 1908.

The President, Dr. Champneys, in the Chair.

Before passing on to the usual business of the meeting, the Chairman briefly alluded, in terms of deep regret, to the recent death of Dr. Cullingworth, mentioning the fact that he was one of the first members of the Board, on which he represented the Midwives Institute from November, 1902 to March, 1905. During the early days of its existence the work of the Board was extremely arduous, and beset with many difficulties, but Dr. Cullingworth never spared himself any trouble. As a colleague he was always generous, fair and most courteous, and in all differences of opinion he showed a loyal public spirit and the spirit of self-sacrifice. After March, 1905, ill-health prevented his accepting re-election, and the Board unanimously passed a resolution of sincere regret for his loss, and desired to place on record their deep sense of the great services he had rendered to it. Several other members of the Board endorsed the Chairman's sentiments, and a resolution was unanimously passed to the effect that the Chairman should write to Mrs. Cullingworth and convey to her the Board's deep sympathy with her, and their deep regret for her and their own loss.

Princess Christian had applied for recognition as a training school for her Maternity Home at Windsor, which trains four pupils per annum, giving them six months' training. After some discussion, the resolution "that the application be granted" was passed *nem. con.*

In the report of the Standing Committee a letter was dealt with from the General Secretary of the British Medical Association as to the question of bringing to the notice of midwives the importance of the earlier recognition of uterine cancer. It was agreed that the General Secretary of the British Medical Association be thanked for his letter, and that he be informed that the Board has already had the subject under its consideration, and proposes to send a leaflet on the subject, prepared by the Chairman at the request of the Board, to teachers and local supervising authorities for distribution among midwives. With reference to a letter from the Clerk of the Worcestershire County Council respecting deaths of infants from pemphigus, it was decided that he be thanked for his letter, and informed that the Board considers that the sanitary officers should be encouraged to prosecute further inquiries into this interesting and important epidemic should the opportunity occur.

In reply to a letter from the Under-Secretary for Ireland as to providing facilities for the examination in Ireland of candidates for the Central Midwives Board certificate, it was decided that the Under-Secretary be referred to the following resolution passed by the Board on January 31st, 1907:—"That the Board realises the difficulties of an extension of the Midwives Act, 1902, to Ireland, but would look with favour on a new Act for Ireland framed on the lines of the present Act."

The Penal Cases Committee reported some 30 women to be cited to appear before the Board on various charges. Their cases will be heard at the C.M.B. on July 9th and 10th. Several convictions of midwives were reported, one being for failure to notify births of children under the new Act. It was remarked that this was the first conviction for this offence.

In receiving the report of the Finance Committee, the Chairman remarked that the time was coming when the Board would have to look for subsidies. The Secretary's report on the April examination showed a total of 298 candidates, of whom 234 were successful in passing the examination, making the percentage of failures 21.5.

The following resolutions, put forward by Mr. Fordham, were carried without opposition:—(1) That it is desirable that an annual report of the proceedings of the Board should in future be prepared and presented to the Privy Council, with a view to its issue as a public document. (2) That, in the meantime, a summary of the proceedings of the Board for the five years ending March 31st last be prepared. (3) That the Privy Council be approached in order to obtain their assent to these arrangements.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD

FRANCE.

Paris, May 24th, 1908.

Injections of Gray Oil.

From time to time cases of mercurial poisoning, due to injections of gray oil, are published, but in reality these injections present no danger if care is taken to observe the rules which should govern this intensive treatment of syphilis. Account should be taken of the condition of the patient before and during the treatment. The majority of practitioners, says Prof. Queyral, neglect to examine the urine of their patients before commencing the treatment; this examination is, however, very necessary, for if albumin is detected insoluble preparations of mercury should not be employed. An examination should also be made of the condition of the teeth and gums, and if their condition is defective they should be treated before having recourse to injections of gray oil.

Further, the patient should be enjoined to pay particular attention to the mouth by using a gargle of chlorate of potash after each meal, to abstain from spiced foods or sauces; and, above all, from alcohol and tobacco, the two great enemies of syphilis. During the course of the treatment the condition of the gums should be examined before each injection, and where they appear slightly swollen or spongy the injection should be adjourned to the following week. The injections should also be suspended if the preceding injection produced induration, for there lies the danger of stomatitis. The induration contains a large quantity of mercury, which may be eliminated at any moment, and if one or more injections were made at the same point a toxic dose would be the result.

The needle, an inch and a-half in length, should be inserted into the muscular mass, about two fingers' breadth above the great trochanter, and care should be taken that no blood comes out of the needle, so as not to expose the patient to the inconvenience of fatty embolus, etc.

As to the quantity of gray oil to be injected each time, the dose should not exceed 1 grain of mercury at the beginning, but this dose might be gradually increased to 2 grains if the patient supports it. A series of 8 injections, covering two months' treatment, should be separated from another series by six weeks or two months.

Polyarthritis Deformans.

Polyarthritis deformans is a malady of nutrition into which enter several pathological elements. In the majority of patients there exists an anterior infection due to gastric fermentations and retention of toxic products. The phenomena of this rheumatism consist in rarefaction and progressive decalcification of the bones. An increase of phosphates, lime and magnesia salts, as well as chlorides, is observed in the urine, while examination of the blood shows a slight decrease of hæmoglobin.

Up to recently, the treatment of this affection was more or less empiric, and consequently uncertain in its results. All kinds of drugs have been tried, and generally without success. Tincture of iodine, however, as recommended by Lasègue and Trousseau, produces an attenuation of the suffering on the condition that it is given in large doses (10 to 60 drops daily).

Unfortunately, the stomach can ill bear this treatment. Arseniate of soda has been prescribed in the form of Fowler's solution, and Guéneau de Mussy employed arsenical baths (2 dr. with 5 oz. of bicarbonate of soda). Salicylate of soda and aspirine, this latter especially, alleviate the painful phenomena, but iodide of potassium, salol trinitrine, cod-liver oil, etc., are of little or no value. The practitioner, says Prof. Robin, will derive more benefit from employment of a treatment addressed to the different therapeutic indications.

If there are gastric fermentations, a severe alimentary *régime* will be prescribed, with antiseptics appropriate to the different ferments. In case of lactic fermentation:—

Fluoride of ammonium, 4 gr.
Water, 10 oz.

A tablespoonful during dinner and supper.

For butyric fermentation:—

Iodide of bismuth (erythrol), 1 gr.
Carbonate of lime, 4 gr.

For one wafer, to be taken during the repast. An excess of HCl is best treated by suppression of animal food, and

Bicarb. of soda, 1 dr.
Phosphate of soda, ½ dr.
Sulphate of soda, 10 gr.

For one powder dissolved in a pint of water, of which a Bordeaux glass is taken on rising in the morning, another at 11 o'clock, at 4.30, and at 9.30 in the evening. Besides, the patient will take an absorbent powder (prepared chalk, calcined magnesia, bicarbonate of soda) after each meal, while the use of table salt will be diminished.

After three weeks of this *régime*, the gastric functions will be about re-established, when stimulating treatment may be adopted. The patient will be given preparations of strychnine, hypophosphites, glycerophosphates, while small igni-punctures might be made twice a week along the vertebral column.

Hypophosphites exercise a special action on the osseous nutrition:—

Hypophosphite of lime,
,, ,, soda, } 10 gr.
,, ,, potash,
,, ,, magnesia,
,, ,, quinine, } 2 gr.
,, ,, of iron,
,, ,, strychnine, ½ gr
Arseniate of soda, 1/5 gr.
Tincture of rhubarb co., 2 dr.
Water, 5 oz.

A tablespoonful at each meal (2).

The glycerophosphates may be given subcutaneously, or in a mixture:—

Glycerophosphate of lime, 1 dr.
,, ,, soda,
,, ,, magnesia, } 15 gr.
,, ,, potash,
,, ,, iron, 10 gr.
Tincture of nux vomica, 10 drops.
Pepsine, ½ dr.
Maltine, 15 gr.
Ext. of kola, 1 dr.
Syrup of orange, 6 oz.

A tablespoonful at each meal.

At the end of a month of this treatment, iodide of potassium with arsenic might be tried:—

Iodide of potassium, 1 dr.
Arseniate of soda, 1 gr.
Water, 10 oz.

Two tablespoonsful daily.

The local treatment is addressed to stimulation of the osseous nutrition, and to check the muscular atrophy accompanying this affection, massage after a sulphur bath of half an hour meets this end.

The bath is composed thus:—

Monosulphide of sodium, 1½ oz.
Chloride of sodium, 3 oz.
Sub.-carb. of soda, 3 oz.
Gelatine, 2 oz.

Gentle active and passive movements may be practised morning and evening. Electricity is daily employed—Faradic currents for muscular atrophy, galvanic currents for pains and as a modificator of osseous nutrition. Baths of heated air (248°) have given relief, while baths of turpentine vapours are appreciated by the patients. Painful attacks may be relieved sometimes by aspirine (10 gr. four or six times a day), pyramidon (6 gr. two or three times a day), or Dover's powder (6 or 8 gr. at night).

Hydro-mineral treatment comprises the thermal waters of La Bourboule, Archambault, Bourbonne-les-Bains or Barèges. Mud baths might be recommended after a season at one of the preceding places. They are found at Dax and Saint Amand.

GERMANY.

Berlin, May 24th, 1908.

RENAL DIABETES.

IN connection with the paper on this subject by Hr. Böllinger, read before the Verein für innere Medizin on March 16th, Hr. Lepine, of Lyons, sent a communication of which a German translation was read to the society by Dr. Magnus Levy, the purport of which was a reminder that M. Lepine had published a communication on the same subject more than two years ago. "I am," he continued, "the more time elapses the more firmly convinced that the sugar in the blood, in opposition to the view of Ascher, exists in a more or less firm combination. My dialysis experiments are in favour of this. The various kinds of glycosuria, without glycæmia, would then be explainable by an absence of that combination. Up to the present no fact is known that speaks for an increased permeability of the kidney for sugar. On the contrary all the labours of myself and Boulud on virtual blood sugar show that the blood sugar under certain circumstances readily becomes free from its combinations.

"That happens for example under physiological conditions in the capillaries of the lungs; it happens in the capillaries of the kidney in the phloridzin dog, and also in other capillary circles; by this is explained the hyperglycæmia that takes place occasionally in certain animals in phloridzin poisoning.

"Like Hr. Böllinger I hold the separation of the blood sugar into that of the plasma and that of the blood corpuscles as very useful."

Hr. A. Plehn then showed a case of

PROGRESSIVE MUSCULAR ATROPHY.

The patient was a workman, æt. 48, about whose family history nothing could be learned. It appeared, however, that his work had always been laborious, and for years he had worked in water in the sewers. He had also carried very heavy weights, for which he had always used the left shoulder. For the last eight or ten years he had suffered from pains in the back and shoulders, and he had noticed a loss of power, and also that the muscles in both upper arms had been getting smaller. Notwithstanding this he was able to continue his heavy employment in a cement works until last December, since then he had not been able, and he sought relief in the hospital for pains and weakness in the arms and back.

In looking at the man the first thing noticed was the falling away of the shoulder blades from paralysis of the serratus. It was excessive, for not only was the serratus anticus almost completely atrophied, but the trapezius up to the upper part and the rhomboideus major. The latissimus dorsi was also affected, and the lower muscles of the back so that it was difficult for the man to straighten himself up. The supra- and infra-spinatus were mostly retained, as was also the levator scapulæ. The triceps and biceps, the brachialis anticus, and the coraco brachialis had mostly disappeared, but on the other hand the muscles of the lower arm had retained their power. The appearance of the deltoid was remarkable; the shoulder portion was atrophied, the arm portion was retained, and if anything, seemed to be rather hypertrophied.

The electrical excitability was in parts completely extinguished, in others very much diminished. The parts of the muscles in which irritability was retained gave slow twitchings to strong direct Faradic currents. There were fibrillary twitchings in the parts in which the retention was partial.

The case was one therefore of complete bilateral atrophy of the region of the nervus accessorius and of certain branches of the brachial plexus. The question now was whether the affection was primarily myogenous or spinal. The speaker believed the lesion to be chiefly a spinal one, a degeneration of the anterior cornu of the cervical cord in the sense of Duchenne-Aran. He thought this from the strikingly equable distribution in the corresponding nerve regions of both sides.

Hr. Cassierer thought the case was one of myogenous dystrophia; atrophy and hypertrophy were present together.

Hr. Rosenstein remarked that such cases were not hopeless from the point of view of treatment. He had seen a similar case in which V. Eiselsberg obtained good function by suturing the two scapulæ together.

Hr. Karewski knew the case referred to; he had had to have the scapulæ separated again on account of the great trouble caused by their being united.

Hr. Plehn, in reply, acknowledged that the nature of the lesion was still uncertain. He was not sure about the hypertrophy of the deltoid. He had seen no change of the facial musculature, although he had looked for it carefully. Oppenheim had also remarked that there were atypical cases that united the symptoms of both diseases. For that reason the case shown was one of interest.

AUSTRIA.

Vienna, May 24th, 1908.

Cysticerci in the Brain.

Falta, at the Gesellschaft, produced a male patient, æt. 58, with cysticerci in the brain. Their presence was diagnosed by the burrows in the skin resembling tubercles or peas on the surface, and which, when carefully examined with a lens, were found to contain the cysticercus. According to the history, the patient suddenly lost the power of speech, the right angle of the mouth had an inclination to fall backwards, while the fingers of the right hand were void of feeling. At a later period convulsive movements of the facial muscles, vertigo and cephalalgia set in. Shortly before exhibition he had had a severe fit.

"Ultra-Konien."

Neumann and Kreidl reported their work of investigating this peculiar constituent of animal milk that does not exist in the healthy human fluid. These researches found it in the mare, elephant, goat and rat. They confirmed its absence in the human subject. On a former occasion this ultra-constituent was discovered in the cat and dog, which excited considerable curiosity, and a strong desire was expressed that further investigation should be made to discover the cause of dissimilarity between animal and human milk. Neumann and Kreidl now affirm that the fine particles present in animal milk and not human are casein, not soluble in ether, but dissolving easily in pepsin and pancreatin, and coagulating with rennet and acids. This is an important explanation of the fact that all the supposed fat of cows' milk will not dissolve in ether. If this so-called fat, however, be dissolved in lye, ether can then be used as a solvent. From these results they consider this ultra-constituent to be a "haptogenic membrane." These ultra-particles must be distinguished from the ordinary coagulation of the milk. By ultra-microscopic examination, the coagulation with rennet or acids will be observed to have fallen in flakes, as distinguished from the fine particles under consideration. The best rennet coagulation is done with 10 cubic centimetres of a 1/10 per cent. acid solution in 100 c.c. of milk; other substances with heat may do the same, and the particles obtained by shaking with either. Escherich thought this was important in the distinction of human milk versus animal milk.

Myasthenia.

Flesch presented a case of sudden myasthenia, which came on four years ago, producing right-sided lagophthalmos and left-sided ptosis with paralysis of the uvula. These symptoms seemed to improve gradually up to nine months ago, when diplopia appeared, which, two months later was followed by double-sided ptosis and general debility, the latter disappearing gradually, but the ptosis still continues. This debility or general malaise is characteristic of the disease, and by repetition of this enfeeblement the patient is reduced to the condition of having to recline when taking food. The Faradisation showed strong muscular contractions at first, which gradually die off until finally no movement can be produced. He also showed a young man, æt. 23, with paralysis in ocular co-ordination where both of the interni muscles were involved. He had double vision, both objects lying in the median line, but somewhat apart and crossed. The converging movement of the eye is impossible, but the pupil still reacted to light.

Atypical Tabes.

Strasser showed a male patient, æt. 50, who, 30 years ago, contracted syphilis, and 10 years ago had the first symptoms of polyneuritis, associated with endocarditis, after a severe injury. The tabes did not appear till five years ago, and greatly improved after a few mercurial inunctions. A little later, however, he was seized with emotional disturbance, anuria, and complete paralysis of the extremities, while sensibility and temperature disturbance was very little affected. In the course of a few days progressive atrophy and degeneration of the paralysed muscles were observed. Hydrotherapy and electric treatment were vigorously pursued with beneficial results; the movement of the muscles soon returned and their volume rapidly increased.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Secretary for War on a Territorial Army Nursing Reserve.—During a visit to Edinburgh on May 21st the Right Honourable R. B. Haldane, M.P., Secretary of State for War, attended a gathering of nurses in the Royal Infirmary, and presented the prizes to those who had been successful in the examinations. Mr. Haldane was accompanied by Miss E. S. Haldane, and among others present were the Lord Provost, Lord Salvesen, Mr. Geo. Berry, Sir Halliday Croom, Professors Wyllie and Greenfield, Drs. Barbour, Bramwell, Macgillivray, Haig Ferguson, and Playfair, and Messrs. Dowden, Alexis Thomson, Cotterill, and Stuart, and a number of other members of the staff. After the formal ceremony was finished, Mr. Haldane expressed the interest he felt in the training and work of those who were present. An infirmary was only possible on the basis of a very high kind of organisation, and a kind of organisation which could only be real when it was based on high science. To his mind, organisation based on science was one of the most necessary needs of the country, and any institution which presented an example of it was of value to the State far beyond its own particular department. Speaking of the advances in the nursing profession, he said that there was little in common between the old and new generation of nurses, except the name. In the old days people looked to the physician and surgeon, and to them only; the nurses came in nobody knew exactly where. To-day the work of the physician and surgeon was divided; the health of the patient and his restoration to health was largely left to nurses. More and more were nurses being called upon to intervene in the affairs of State and of public life; they were wanted for the business of local self-government, not to care merely for the sick, but for the study of those who came near the sick—the poor. They were wanted in great hospitals, in private life, and in country districts. The demand was now so great that the supply was hardly adequate. He had been very busy trying to fashion out a comprehensive organisation for the country for national defence. That meant organisation for war, and organisation in peace which was based on preparation for war. He had had to survey the whole field, and in the process of building up he came to a point where the work of Army surgeons and Army nurses became vital, and where further organisation was necessary. So remarkable had been the progress in Army medical work that they had been able to reduce the provision which they had to make for the sick and wounded by a considerable percentage. They had been able to make far better provision, which presented them with a smaller percentage of men who required to be deducted from the fighting force. That is, they were able to restore people to work more quickly than under the old conditions. They had created a reserve of nurses—those who had engaged with the State to go to the theatre of war, and there do their part in the organisation for the treatment of the sick. This had been carried out so far as the regular forces were concerned. As regards the second line, or home defence—the Territorial or Home Army—he hoped before long to see in operation an organisation of Territorial Army nurses, who would take the same part in home defence as would be taken by their sisters who went abroad with the troops. These things showed them what a far-reaching profession theirs was—he knew of none which had more scope than the profession of the highly-trained nurse.

New Fever Hospital for Dumfriesshire.—This new hospital, situated about half a mile from Lochmaben, was formally opened on May 16th, by Lady Buchanan Jardine, of Castlenuek. It consists of an administrative block with kitchen annexe, providing quarters for a matron and eight nurses. There are three pavilions of corrugated iron for scarlet fever, typhoid, and diphtheria, and two observation wards. Accommodation is provided for 28 patients, being one per 813 of the population of the district.

Dr. Leslie, on behalf of the Local Government Board, spoke very highly of the planning of the hospital.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.—At a meeting of the College held on the 18th inst., the following gentlemen were elected Fellows :— Leo F. Bianchi, L.R.C.S.E., M.R.C.P.E., D.P.H., Edin.; Walter H. O. Garde, L.R.C.S.E., Staff Surgeon, Royal Navy; John L. Gilks, M.R.C.S., Eng.; Dirk J. H. Hamman, M.B., Ch.B., Cape Colony; William C. Horton, M.B., Ch.B., Birmingham; John Jardine, M.B., Ch.B., D.P.D., Penicuik; James B. Lockerbie, M.B., Ch.B., Dumfries; George Ross, M.B., M.R.C.S., Eng., Melbourne; Charles W. Smith, M.B., L.S.A., Sheffield; and Raymond H. Swindells, M.B., Ch.B., Fairfield.

THE BATHGATE MEDAL.—The medal and set of books presented to the College by Colonel William Lorimer McPhune Bathgate, F.R.C.S.E., Lecturer on Materia Medica in the Extra Academical School, was awarded, after the usual competitive written examination in Materia Medica, etc., to Miss Lucy Mary Muir, 12, Buccleuch Place, Edinburgh.

BELFAST.

THE IRISH UNIVERSITIES BILL.—This Bill has been discussed at several public meetings in Belfast during the past week, and as a general result one may say that, while certain extreme parties maintain their first strong opposition to all that Mr. Birrell offers, there is, on the whole, a tendency to a more reasonable attitude in many quarters. It is seen that, as far as Parliament is concerned, the opposition to the Bill is almost negligible, and many who at first objected to it from a deep-rooted objection to anything that looked like sectarian education, are now inclined to accept the Bill as the best way out of a difficult situation, and concentrate their energies on obtaining such amendments as they think would improve it. The first meeting of the week was that of the so-called Royal University Graduates' Association, which is really only an association of those who are opposed to a Belfast University. In spite of great efforts to raise a meeting, the attendance was very small, and, as far as the medical profession went, representative men were conspicuous by their absence, the Chairman and Secretary, Drs. John Campbell and R. W. Leslie being the only hospital men present out of some forty or fifty holding hospital appointments in the city. Several lawyers and a number of clergymen were present, and took part. They were brought there to curse, and curse they did with a hearty goodwill. There were, however, no new arguments against the Bill. Perhaps the most interesting remark was that of Mr. R. J. McMordie, who is reported to have said that three men had been marked out for knighthoods, apparently as a reward for supporting Mr. Birrell!

The Ulster Liberal Unionist Association, which includes a large number of influential business men, held a largely attended meeting in the Ulster Reform Club on the 22nd inst. After reaffirming their objection to any form of sectarian education, they proceeded to advocate certain amendments in the Bill. These are:—(1) The appointment of all officers and professors by the Crown. (2) The admission of affiliated colleges only by the decision of Parliament. (3) The continuance of the present form of declaration made by professors in the Queen's Colleges, promising not to interfere with the religious opinions of any of their pupils. (4) That the charters of the new Universities should be fully discussed by Parliament before being presented to his Majesty for signature. Probably these amendments would be generally acceptable in Belfast, though it is very doubtful if some of them would be received with favour in Dublin.

The Ulster Unionist Council met in Belfast on the 22nd inst., and passed a resolution approving the action of the Ulster Unionist members in opposing the Bill, and "strongly urging them to press for such amendments in committee as will remove from the Bill all provisions which are at variance with the principles of religious equality and freedom from ecclesiastical control."

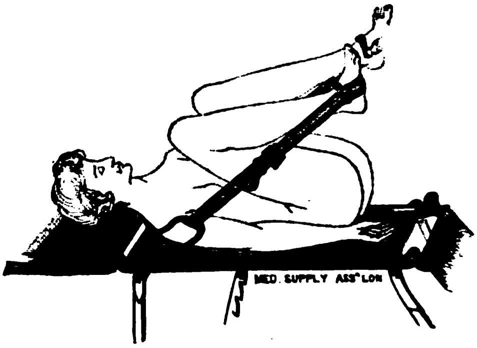
PUBLIC HEALTH.—In the report of the Belfast Health Commission, lately published, the chief cause of the prevalence of typhoid in the city was suggested to be the consumption of contaminated shellfish, especially cockles, from the shores of Belfast Lough. Professor Symmers has, consequently, been making further examinations of these at the Bacteriological Laboratory at Queen's College, and he reports that every specimen examined was unwholesome, most of them swarming with colon and allied bacilli, undoubtedly derived from the sewage discharged into the Lough. Active measures are now being taken to prevent the sale of these cockles in the city. Large quantities are exported. It is said that they are used for bait in the North Sea, but their destination is being carefully watched. In medical circles the general opinion is that the report attaches too great importance to this source of infection, for though it is undoubtedly one source, it is far from being the only one. Numbers of cases of typhoid occur among the better classes of the city, who never see the cockles, and some less obvious cause must be sought to explain these cases.

LETTERS TO THE EDITOR.

CLOVER'S CRUTCH SUPERSEDED.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The accompanying illustration represents a simple plan for obtaining the lithotomy position, more especially in private practice, the strain on the shoulders being equable and the rubber-covered collar being more comfortable than the strap; the appliance is light and portable, and can be carried in any surgeon's carriage. When adjusted the patient is not attached in any way to table, or couch, an obvious advantage, and the cross-bar or crutch dispensed with altogether.



The appliance has been suggested by me, and neatly made by the Medical Supply Association, of 228 and 230 Gray's Inn Road, London.

I am, Sir, yours truly,
ALEXANDER DUKE.

London, W.
May 25th, 1908.

CHARGES IN NURSING HOMES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some months back a letter appeared in your columns on the above subject. It would be most interesting to hear the experiences of other medical men in this direction. A recent incident has forced the question upon my attention in a most unpleasant way. A patient had a little boy at school in a medium-sized town on the upper reaches of the Thames. One day she was informed by telegram that the child had been taken with measles. On going to the school she was told the boy must be removed, and she accordingly took him to a nursing home in the neighbourhood. She was charged four guineas a week for the boy, a small mite nine years of age, two guineas a week for the special nursing of an infectious case, with extras of every conceivable kind, and a fee for disinfecting everything at the end of the stay. All this seems excessive for the medical care of a small boy in what is, after all, not a serious condition if properly nursed.

In any case why should not medical men co-operate and have their own nursing homes under their own management, where patients could be well looked after at fair charges. It should not be beyond the art of our professional brethren to organise a service of this kind, especially away from the neighbourhoods where rents are costly. At present the patient has often to pay so much for the nursing home that there is no money left for the medical attendant. It is the old story of everyone making money out of the patient except the man whose services are absolutely essential. It seems to me that the matter is one that might most advantageously be received in the columns of your valuable journal.

I am, Sir, yours truly,

R. Clark.

May 22nd, 1908.

THE POPULATION QUESTION.

To the Editor of The Medical Press and Circular.

Sir,—Your correspondent "A Student in Sociology" has once more broached a stupendous question. It would demand an essay to deal fully with it. It needs forcing upon the attention of the people and their leaders. It, unfortunately, cannot be discussed freely in public, on the platform, in the pulpit, or through the newspaper press, and you are conferring a benefit by generously opening your columns to it on this occasion. It is quite evident that the British Empire will not endure unless these islands possess an exuberant population of the highest physical and moral quality. We shall be in time swamped by weight of numbers if we do not increase with due rapidity; whilst it is to me tolerably evident that artificial restriction of fecundity as now practised must lead to degeneration. It is a system of artificial selection calculated to favour the survival of the unfit. This is the effect it is producing in France. It matters not how unfit, physically and mentally, the first-born children may be, the marriage of the one or two girls is ensured among the well-to-do and wealthy classes by provision of a fortune suitable to their rank. The boy in the same way is provided for, and he is enabled to marry in due course. If the family were numerous it is evident that those most fitted for matrimony would, as a rule, alone marry. No Frenchman marries "for love"; and without a fortune no girl can find a husband, however superior her physical and mental endowments. Then one would like to know what are the effects of these marital and marriage customs upon the indivudal parents and their offspring, and ultimately upon the race. The father remains without the stimulus to exertion which a larger family would impose upon him, and the mother has her maternal instincts suppressed to a great degree. The wealthy give themselves up to a life of pleasure, the pursuit of amusement; and for this Paris is the goal ardently striven for by all rich French people. Then the children of the very rich are almost invarably "spoilt," whilst among the less wealthy a position for the boy being found at home, all foreign enterprise, all movements of colonisation are rendered impossible. Discount it as one may, one cannot refuse to accept as an approximation to the truth the type of young man that the French novel writer depicts, and admires as his hero. Readers of French fiction from the pen of leading writers well know how constantly the hero is a sensual, cowardly, hysterical degenerate, devoid of all the qualities which have at any rate hitherto formed the ideal of manliness among our British folly.

I am, Sir, yours truly,

A Surrey Doctor.

May 22nd, 1908.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

Operation for Acute Appendicitis.—Mr. Peyton Beale operated (on behalf of Mr. Carless) on a man, æt. about 35, who had been admitted with the following history: Three weeks ago he had pain in the abdomen, the onset of which appeared to be gradual and not localised to any particular spot; he described it as colicky. He then saw a doctor, who gave him aperients and fomented the abdomen. The pain became less until three days prior to admission, when he suffered sudden acute pain, which he referred to the left iliac region. On admission the man did not look acutely ill, he was able to walk, his temperature was about 100°. The abdomen was distended, but quite soft (it was reported to have been rigid until a day before his admission); it was tympanitic everywhere except in the right iliac region where there was obvious dulness. On turning the patient on to his left side, this dulness disappeared. There was slight pain on pressure over the right side of the abdomen. The patient had had no trouble in passing urine, his bowels had been opened several times by means of saline aperients, but an enema administered soon after admission was returned unaltered. The pupils were somewhat dilated. Mr. Beale stated that he believed the case to be one of acute appendicitis with general peritonitis, and a large quantity of pus and gas in the abdominal cavity. He said that this was not infrequently the last stage of an acute appendicitis, and the absence of what might be called acute abdominal symptoms was due to a great absorption of toxins from the peritoneal cavity into the blood stream leading to a condition of septic intoxication, so that the patient appeared not to be so ill as he really was. He had seen previously cases of the same kind in which the patient had walked a considerable distance (two miles), and the abdomen was full of pus; they might be termed cases of ambulatory acute appendicitis. The septic intoxication was so great that pain was practically absent, and the patient had an extraordinary appearance of general well being. If left alone sudden and violent collapse would supervene, and this was followed by delirium and rapid death. In the present case the patient was taken into the theatre at once and anæsthetised. The abdomen was opened in the right side as far back as possible, that is to say, at the junction of the right iliac and lumbar regions. On opening the peritoneum a large quantity of foul smelling gas and pus issued at very considerable pressure, all the coils of intestine which were visible were thickly coated with lymph, and the appendix could be felt adherent to the posterior abdominal wall. The peritoneal cavity was rapidly irrigated with a 1 in 20 solution of lysoform in hot water, and a large gauze drain inserted. Mr. Beale thought it inadvisable to attempt to remove the appendix, his experience of this particular class of case being that the best chance for the patient was to open the abdomen rapidly, to let out the pus, and to wash away that which was in the neighbourhood of the wound, and insert a large gauze plug, the whole of which proceedings would occupy not more than five minutes. If the patient recovered he would remove the appendix by the ordinary incision in the iliac region. He considered the posterior incision which he had made in this case to be very useful, in that it afforded perfect drainage, it was not liable to be afterwards the seat of a hernia, and it left the iliac region free for the subsequent removal of the remains of the appendix.

OBITUARY.

JOHN WILLIAM CARPENTER, M.D.St.And., M.R.C.S.

We learn with much regret of the sudden death of Dr. John William Carpenter, of Goudhurst, which occurred on May 14th, from apoplexy Dr. Carpenter, who was 79 years of age, practised for some years in the district, and his kindly actions towards the poor had won for him very high respect and esteem. At the inquest, held by Dr. Joyce, Margaret Jane Cork, deceased's housekeeper, stated that she was talking with him in the garden about a quarter to twelve when he suddenly fell back. He had been mowing, and was holding a scythe in his hand. She caught him as he fell, but he died immediately. Dr. W. E. Fielder on arrival found that Dr. Carpenter was dead. He had since made a post-mortem examination, and found the cause of death was an apoplectic fit. The jury returned a verdict of "Death from natural causes."

GEORGE ALOYSIUS WILSON, L.R.C.P.ED., L.F.P.S.GLASG.

WE regret to record the death, which took place on May 16th, at Blackburn, of Dr. George A. Wilson, the oldest medical practitioner in that town. The deceased gentleman, who was 72 years of age, was a native of Ribchester. He took up the study of medicine at Glasgow, and when about 35 years of age was awarded the Dr. James Watson gold medal and a purse of gold, and granted the licence of the Faculty of Physicians and Surgeons of Glasgow and of the Royal College of Physicians of Edinburgh. He qualified in 1872, and commenced practice in Blackburn, and continued there without interruption up to the time of his death. The late Dr. Wilson was of a retiring disposition, and never entered into public life, but was, nevertheless, well-known throughout the town, and there are many reminiscences of his unostentatious kindliness and generosity to those of his patients who were in adverse circumstances. In his day Dr. Wilson had an extensive practice in the town and district, and about 25 years ago he was a familiar figure on horseback in the Mellor and Balderstone neighbourhood.

SPECIAL ARTICLES.

THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE UNIVERSITIES BILL.

WITHIN the next few days it will fall to the lot of the one-time champion of undenominational education—the Chief Secretary for Ireland—to decide whether or not his shall be the hand to destroy what would otherwise shortly become the only undenominational school of medicine in Ireland. The School of the Royal College of Surgeons in Ireland was founded shortly after 1784 as the after-result of a charter which stated that "the regulation of the profession of surgery is of the utmost importance to the public, and highly necessary for the welfare of mankind," and which empowered the College "to establish a reliable and extensive system of surgical education." We are unable to state what is the exact number of medical men who since that time have owed their education to this School, but some idea of their number may be gathered from the fact that at the present time there are 2,932 licentiates on the roll of the College. Thus it is obvious that, in one fundamental particular of its charter, the "reliable and extensive system of education" founded by the College has been successful. In another fundamental particular the College has been no less successful. The standard of medical ethics in Ireland is admittedly one of the highest, if not the highest, in the world, and it has been the fruit of the control exercised by this College and by the Royal College of Physicians. Therefore, if the College is to fall, it is not to fall because it has neglected its duty, but for some other entirely different reason. What is this reason, which is sufficiently powerful to make a great educational champion turn against his principles? Presumably we shall be told that it is "expediency." Expediency is notoriously a word of unreliable parentage, and never will it better justify its origin than in the present case. It is "expedient" for the sake of saving the Treasury a few thousand pounds annually to destroy the Colleges which are responsible for the control of the medical profession in Ireland and for the guidance of the State in affairs touching the public health. It is "expedient" for the sake of removing all competition from the way of a rival to destroy the only source of medical education which men of all creeds and politics can in the future regard as undenominational and purely professional. It is a well-known fact that for many decades the School of the College of Surgeons was the only one to which Catholics could resort without incurring ecclesiastical censure. Then, as now, it admitted all and sundry to its lectures, its degrees, its Council, and its Presidency, and then, as now, there was no taint of sectarianism. Is the abolition of such an institution in accordance with the spirit of the present age, and is the hand of Mr. Birrell an appropriate agency for effecting such an abolition? We are entirely ignorant of the identity of Mr. Birrell's "ecclesiastical scouts" or "medical advisers," and we cannot think that either the one or the other desire to lead him into the perpetration of what, in its stupidity, is worse than a crime. We therefore would fain think that the "expediency" of his policy was the result of Treasury influence alone.

It is an old adage that the foolish man begins to build his house before he has counted the cost, but, even if he does, he has the excuse that he must have a house. On the other hand, what defence can be brought forward for the man who begins to pull down his house before counting the cost? Yet, what else is Mr. Birrell doing? The destruction of the College School involves a severe loss to medical education, and to this we have already referred. It, however, involves something more, seeing that it cannot be accomplished without drawing in its train the destruction of both Royal Colleges. The cost of this must be borne by Ireland as a whole, and by the licentiates and fellows of the two Colleges; but the reputation of Mr. Birrell and of the present Government will also contribute to it, and once again an English statesman will be credited with the destruction of a successful institution in Ireland. Another member of the Cabinet gave Mr. Birrell good advice in the course of the second reading of the Universities Bill, by saying that the Government desired to create new institutions in Ireland and not to destroy existing ones. Will Mr. Birrell take this advice, supported as it is by practically the entire medical opinion of the United Kingdom, or will he, with a cheerful jest once again, let his good intentions get the better of his principles?

BURROUGHS WELLCOME'S HEMISINE.

ONE of the important organic drugs of recent years is undoubtedly that produced from the suprarenal gland. Like all products of organic origin its preparations are subject to changes which more or less impair their therapeutic value. That defect is overcome by the careful production of "Hemisine," the active principle of the medulla of the suprarenal gland, which is stable and active both in the fluid form and in the dry, from which a solution can be readily procured. Apart from its action as a local vaso-constrictor and anæsthetic. Hemisine has a wide and general action. It is given, for instance, in atonic conditions of circulation and of nervous system, asthma, purpura and dilated heart. Curiously, it has proved of little use in Addison's disease; while it is positively harmful in hæmorrhage from tubercular lungs. One great feature in Burroughs Wellcome's preparation is that it is standardised, an essential thing in dealing with so potent a drug. There are a number of convenient compound preparations issued in soloid and tabloid form, such as hemisine with atropine, cocaine, eucaine, and so on.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Fractures Complicating the Elbow-Joint.—S. Cole, in a paper (*Post-Graduate*, April, 1908) on fractures about the elbow-joint, deals briefly with the commoner forms of fracture, their diagnosis and treatment; then discusses more fully fracture at the upper end of the radius, and advises the following methods of treatment: In fractures of the head of the radius, treatment by plaster of Paris circular bandage, the forearm flexed to a right angle and carried just a little beyond mid-pronation in the direction of pronation, the elbow-joint having been first liberally surrounded by absorbent cotton wool held in place by a firm muslin bandage. Later, if sufficient interference be caused by any fixation, sufficient to justify operative measures, removal of the fragments and an effort to restore the function of the joint may be made. In cases where the neck of the radius is fractured, immediate removal of the fragments should be done, as fixation and loss of function must follow any other form of treatment. The same treatment is all the more imperatively demanded if fracture of the neck of the bone be complicated by fracture of the head as well. If the ulna has been fractured as well, avoid any open operative interference until a sufficiently long time has elapsed to show what permanent loss of function has been sustained, and what probable improvement can be obtained without operation. G.

Adipositas Dolorosa.—Sezary (*Revue de Médecine*, December, 1907) describes four cases of adipositas dolorosa, characterised by local or general deposition of fat, pain, asthenia, and psychic disturbances. The first patient, in whom one segment of the body was affected, also presented sensory disturbances, but there was a possible complication by alcoholic neuritis. While all of the cases occurred in women, there was no ætiological reason for assuming the hypothesis that the adipositas dolorosa was in any way connected with changes in the thyroid or in the ovaries. In two of the cases the disease developed soon after childbirth. In none was there any relation to the menopause. One of the patients suffered from syphilis, another from tuberculous disease, a third from glycosuria. Dr. Sezary mentions a fifth case of adipositas dolorosa which he had seen in a patient who also had aortic insufficiency and was probably syphilitic. The symptoms of this rare disease are by no means constant, or are only present to such a slight degree that they may be difficult to detect among other possibly obscuring symptoms. The obesity may be either diffuse or nodular, or it may affect only one segment of the body. The fatty tissue seems to be specially liable to develop after one of the attacks of asthenia, ; the tissue is extremely sensitive to pressure; ecchymoses are very readily produced; they are, in all probability, due to an instability of the vasomotor apparatus. The swellings at first, if examined, show the appearances of soft, rather œdematous tissue, and this later on is followed by the formation, deposition and gradual accumuation of fat. G.

Prostatic Hypertrophy.—After examining serial sections from 26 cases of prostatic hypertrophy, Dr. Raski (*Wien Rundschau*, No. 8, 1908) can only arrive at negative conclusions concerning the cause of the hypertrophy. He thinks that Ciechanovski is incorrect in thinking that the hypertrophy is caused by inflammatory narrowing of the ducts and consequent retention of the glandular contents; he is also unable to verify the intra-prostatic sphincter theory of Motz and Peronau. In 18 of his cases there were positive findings opposed to the teaching of Finger, who says that the hypertrophy follows as the result of chronic prostatitis. The author agrees with Bier that the hypertrophy is not the result of hyperæmia, but that both the hyperæmia and the hypertrophy are due to some unknown process or processes. He also holds that since there is such variation in the type of hypertrophy found in these cases of prostatic enlargement, in all probability the ætiology must also vary to a considerable extent. G.

Intra-Peritoneal Rupture of the Bladder.—O. Nordman (*Deutch. Med. Woch.*, April, 1908) thinks the most important symptoms in making a diagnosis are tenseness and rigidity of the abdominal muscles, and an unfulfilled desire to pass water. Strictly aseptic catheterism may be attempted, and, should this have no result, immediate laparotomy and suture of the bladder should be resorted to. If there is no purulent peritonitis, Nordman merely washes out the peritoneum with saline solution, then sutures the bladder, and completely closes the abdominal cavity, using in the bladder a retention catheter, keeping the patient sitting up in bed and giving urotropine or some similar drug by the mouth. He believes that it is never necessary to tampon or drain from the sutured bladder through the abdominal wall. The results he has obtained seem to justify this opinion. G.

Anatomy of the Pancreas in Relation to its Disease.—Mayo Robson (*Brit. Med. Journ.*, May 16th, 1908) points out that the relations of the pancreas to the aorta and vena cava, to cœliac plexus, the spleen, the left suprarenal and left kidney, the portal vein, the duodenum, stomach and colon, and even the uterus during pregnancy, render any attempt at even partial excision somewhat difficult. In disease invading the distal part or the tail, extirpation is practicable, and in certain cysts and tumours justifiable. Severe injuries of the pancreas not operated on terminate fatally in nearly every case. Surgical treatment gives much more favourable results. No hard-and-fast rule can be formulated as to the method of treatment. The injured part must be exposed, and either ligature of vessels or suture of surfaces adopted; but gauze tampons and drainage form important features in any of these operations. It is important to remember that the head of the pancreas sometimes overlaps and even embraces the second stage of the duodenum. Swelling of the head may lead to obstruction of the gut. An abnormal tail has caused acute obstruction of the third part of the duodenum. In cystic disease of the pancreas, the peritoneal relations, taken with the site of origin of the cyst, are responsible for various anatomical relations. Thus the cyst may be situated above or below the stomach, and may resemble a gall-bladder, right or left kidney, cæcal or mesenteric tumour. The retroperitoneal position of the organ is an important fact to notice. A collection of pus in some cases of suppurative pancreatitis may be reached from the loin, especially the left, by an incision in the costospinal angle. The variations in the ducts of the pancreas and its relations to the common bile-duct are significant. In a fatal case of acute pancreatitis a gall-stone was found reaching the bile papilla and converting the bile and pancreatic channels into a single duct. The author considers that the treatment of acute pancreatitis is no longer in doubt, and that many lives may be saved by abdominal section, incision of the inflamed gland, and free drainage, if operation has not been delayed too long. He believes that catarrhal jaundice is usually due to catarrh of the pancreas, the swollen head of the pancreas compressing the common bile duct. As regards the diagnosis of interstitial pancreatitis, the author says a correct opinion may be formed in a large majority of cases from the information obtained by the careful physical examination of the patient, a knowledge of the history of the case, and the result of chemical and microscopical examination of the urine and fæces. In discussing chronic pancreatitis in relation to diagnosis, it is pointed out that the original interstitial pancreatitis may pass on into the interacinar variety in which the islands of Langerhans become involved and glycosuria ensues, or the condition may pass on to complete cirrhosis with the same results. Glycosuria is by no means a common symptom of pancreatic disease. The author believes that cholecystoenterostomy to be the operation of choice for the treatment of interstitial pancreatitis, and only in case of absence or contraction of the gall-bladder, with great adhesion, should cholecystotomy or choledectotomy be done. S.

Arthroplasty and Ankylosis.—Whitacre (*Lancet Clinic*, April 18th, 1908) reports two cases in which joints were made in the knee for the treatment of bony ankylosis, which had taken place as the result of disease. The author's method of treatment follows the teaching of Murphy, of Chicago, and depends on the formation of a hygroma. The result is accomplished by interposing between and completely covering the bone ends by a flap of fat-bearing aponeurosis. The author points out that the operation can be done in the mandibular, hip, shoulder, elbow, and knee joints, and the prognosis as to the ultimate results is in this order: The operation gives the best results in the mandibular joint, and is least satisfactory in the knee. Case I.—Patient, a girl, æt. 22, suffered from acute arthritis of the knee, which, in spite of treatment, led to bony ankylosis. A lateral incision was made, beginning at the lower margin of the knee-joint and extending up the thigh a distance of about 10 inches. There was a similar incision on the inner side of the limb 6 inches long. No synovial membrane or articular cartilage could be found at the operation, and the crucial ligaments were gone. The capsule and restraining connective tissue was freely dissected away, and the lower end of the femur sawn off. A wide flap of fascia, with the subcutaneous fat, was removed from the outer aspect of the thigh, and drawn through the joint between the opposing bone ends in such a way as to cover the denuded end and sides of the femur completely. This flap was held in position by interrupted catgut sutures. The wound was closed and the limb put up in extension in plaster of Paris. In a month the plaster was removed, and passive movement commenced. In five weeks the patient was able to bear the weight of the body on the limb without pain. When discharged five weeks later the patient was able to walk without any support or assistance. Extension was almost complete, flexion within 10 degrees of a right angle without pain. At present, eight months after leaving hospital, there is no hyperextension or lateral movement. Active and passive flexion can be carried out to an angle of 90 degrees painlessly. The patella is movable, and the joint is not sensitive. The joint is not sufficiently strong to enable the patient to advance the leg in walking upstairs, but the author expects this power to be likewise regained. Case II. was similarly treated, but the results up to the present have not been so satisfactory. Nine months after the operation there is some lateral movement at the joint, and the patient requires a temporary brace with a hinge at the knee. S.

Fracture of the Patella Treated by Mobilising the Lower Fragment.—Lynn Thomas (*Brit. Med. Journ.*, May 16th, 1908) describes a case illustrating this method of treatment. The fracture of the patella was of 11 months' standing, and a gap of 1½ inches existed between the fragments. At the operation, as the fragments could not be got within half an inch of one another, it was decided to attempt to bring the lower fragment towards the upper by immobilising it. This was readily done by Kocher's curved external incision and chiselling off the tubercle of the tibia. Care was taken not to detach the tendinous and periosteal attachment along its inner edge. By forcible traction upon the lower fragment of the patella and its ligament, the fragments were soon brought into contact, and their bared surfaces were kept in apposition by means of two loops of silver wire. The tubercle of the tibia retained considerable strength of anchorage in its displaced position by means of the untorn fibrous attachments of the ligamentum patellæ on its inner side. The immediate result, and in time the functional result, was satisfactory. S.

Prolapse of the Inverted Bladder through the Urethra.—Leedham-Green (*Brit. Med. Journ.*, April 25th, 1908) reports the following case:—A girl, aged 18 months, was admitted to hospital with a small swelling which had recently appeared between the labia. A similar swelling had been noticed when the child was a month old, but had disappeared on bathing with hot water. On examination a red soft protrusion about the size of a walnut was seen between the labia. It was covered by mucous membrane. The small openings of the ureters were distinctly visible on either side of the prolapse, and from them urine was ejected in the characteristic manner. Under an anæsthetic the prolapse was easily reduced through the dilated urethra, which was large enough to admit the little finger. The child was otherwise healthy and normal. Cure was effected after some difficulty. Strapping the buttocks and thighs together with catheterisation was first tried, but failed. Packing the vagina with iodoform gauze for some time was also unsatisfactory. Finally, under an anæsthetic, a small amount of liquefied hard paraffin was injected into the periurethral tissue at the neck of the bladder. This method was perfectly successful, and when the patient was seen four months later she had perfect control over the bladder. S.

Serious Visual Defects in Responsible Marine and Railway Servants.—Dr. Galloway (Aberdeen), early last year, recorded the case of a captain of a Government cruiser suffering from tobacco amblyopia, a congenitally colour-blind trawl skipper, and a myopic express engine driver; and he now (*Ophthalmoscope*, May, 1908) records five more very similar cases:—(1) An engine driver, æt. 32, in railway service 14 years. Three years ago he was passed as a driver, having been examined by a lay inspector and superintendent. Vision of right eye = 6/24, left = 6/60; with correction both eyes = 6/6. (2) Another engine driver, æt. 45, who had passed eyesight tests 5 years and 1 year and 9 months previously. His vision was: right eye = 6/24; left eye = 6/18; and with + 2 both eyes = 6/6. Dr. Galloway ordered both these men glasses, and told them to wear them on the sly, as they are prohibited. (3) A trawl fisherman, æt. 26, who had been mate of his boat for two years, and had frequently kept a look-out. Vision: right eye = 6/36; left eye = 6/60; and with correction each eye = 6/6. (4) A trawl fisherman, æt. 28, had been nine years at sea, and for the past four years had been constantly in sole charge, and the only one on the look-out. With Holmgren's wools he was shown to be quite colour-blind. (5) Mate of a trawler, æt. 26, had been eight years at sea, and for four or five had been frequently in full charge of his boat. He obtained his mate's certificate because he had acted as mate for twelve months. There was no Board of Trade examination. As he was looking for skipper's certificate, he came to Dr. Galloway to be tested. With Holmgren's wools he matched bright green with the red skein. The author does not comment on the above cases. We suppose he does not deem it necessary. M.

A suspected case of cerebro-spinal meningitis has arisen in the Weaste district, and is under the observation of the Salford Medical Officer of Health. The patient is in a serious condition, and as there are complications it has not yet been possible to determine whether the case is really one of spotted fever.

An epidemic of recurrent typhoid has broken out at Moscow. The hospitals are overflowing, 2,000 patients being already under treatment, while 75 to 100 fresh cases occur daily. The municipality has asked the military authorities to transform the summer barracks into a typhoid hospital.

MEDICAL NEWS IN BRIEF

The Irish Universities Bill.

THE Committee of the Catholic Graduates' Association has drawn up an important memorandum on this Bill and on the draft charters of the proposed Colleges. The committee unhesitatingly accept the test Acts, and would open the emoluments of the new Universities to all-comers, but they wish to express the opinion that they regard as a serious defect the fact that there is to be no protection for the Catholic religion or for Christianity.

The new University, the memorandum declares, will set out under limitations strictly imposed on it by an outside Statutory Commission. The essential liberties of each College may be secured or be impaired to almost any extent by this Statutory Commission. As, therefore, the future usefulness or futility of the new institution depends on the constitution and the work of the Commission, we regard its composition as a matter of the utmost gravity.

The Commissioners should represent not only science, medicine, and law, but especially Irish studies, and philosophy embracing the social sciences and economics.

The Committee protest against the limitation of the autonomy of the University implied in Clauses 1 and 2 of Section 19 of the draft Charter of the University, and state that, however desirable it may be for the Senate to call in professors from other Universities to take part in its examinations either as assessors or as joint examiners, a University worthy of its own self-respect must feel it its duty to resent the form of coercion contemplated by those clauses which, if adopted, amounts to a vote of non-confidence in the capacity or the honesty of its own teaching staff. It is their strong opinion that the Senate should be allowed a discretion to call in extern examiners to assist their own professors in the examinations in a subordinate capacity.

An examination of the composition of the Senate of the University and the Governing Councils of the constituent Colleges shows that the autonomous ideal which was so strongly advocated in the report of the Robertson Commission has been completely displaced. In the scheme set out in the Irish Universities Bill the representatives of the professors and graduates—the men whose special knowledge and whose duty and interest all coincide in making the most apt instruments in the College administration—number only 11 out of 33. Under the Robertson scheme professors made up more than one-third of the Council; in the Bill they number less than one-fifth.

The Committee's opinion is that the management of all collegiate affairs, with the sole exception of the appointment of professors, should be placed in the hands of a College Council elected on purely academic lines.

They regard as a radical defect in the Bill the absence of any clause providing for life-tenure of the teaching officers of the University, and to the absence of any specific indication of what would be considered just grounds for dismissal—a bare provision is made authorising the dismissal of an officer. They believe it of vital importance that professors in the new University should hold office for life or good conduct.

On the question of endowment they declare that the proposed annual grant of £32,000 is manifestly insufficient.

Affiliation, by which the Committee mean recognition of professors in certain subjects, should be, they consider, strictly limited. The present affiliation clauses are too vague, and open the way to grave abuse.

Medical Sickness and Accident Society.

THE twenty-fifth annual general meeting of this Society was held on Thursday last, in the room of the Medical Society of London, when the report of the committee for the year 1907 was submitted and approved, an excellent position of the Society being shown in its increase of members and funds at its disposal.

During the year the membership had increased by 95, the total at the end of 1907 having reached 2,583, all male members of the medical profession or licentiates of dental surgery practising in the United Kingdom. Its funds now amount to £215,039, including an investment reserve of £11,031. The amount paid in sickness benefit was £12,700, being the largest yet disbursed in one year, whilst the annual sickness premium income amounted to £15,976. Great economy is shown in the management expenses, a large balance to the credit of the fund resulting thereby. Over £130,000 has been disbursed as sickness benefit since the Society started in 1884.

Medical Officers in Collieries.

IN pursuance of a suggestion that the South Wales Miners' Federation should, in conjunction with the British Medical Association, draft a scheme which would be satisfactory both to the workmen and the medical fraternity, whereby colliery doctors should in future be appointed and paid direct by miners' committees in the several districts, a joint meeting was held in Cardiff on May 15th, the attendance including Mr. W. Abraham (Mabon), M.P., Mr. Thomas Richards, M.P., Mr. A. Onions, Dr. Maclean (Cardiff), and Dr. Evan Jones (Aberdare). Arrangements were made for a further conference.

Anthrax Investigation Board.

A MEETING of the Anthrax Investigation Board was held on May 21st, at the offices of the Bradford Chamber of Commerce, the Lord Mayor, Chairman of the Board, presiding. It was decided to take steps to arrange, if possible, for the subject of anthrax to be raised and discussed at Glasgow in July. The question of the effectual saturation of bales of wool with a germicidal disinfectant was raised, especially with regard to the difficulty of thorough penetration without the bales being opened up and the wool or hair loosened.

Dr. Eurich reported that since the last meeting of the Board in March three cases of anthrax had occurred; one was fatal, one recovered, and the third was still under treatment. Further experiments as to the disinfection of bales had been carried out, but he was not yet in a position to report finally. During the same period he had examined 135 samples of wool, hair and dust. Of these 59 were bloodstained and represented 45 lots, and of these 59 he found anthrax in 8. He also found anthrax in a sample of shoddy blend. Dr. Eurich stated that so far as experience went, cases of anthrax arose with persons who had not been for a lengthened period engaged on the work in the exercise of which they had caught the infection. Discussion took place as to what was meant by "damaged fleeces" as referred to in the Home Office regulations.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—L. G. H. Furber, E. Lakovski, G. R. McCowen, and G. Rollason.

Royal College of Surgeons in Ireland.—Fellowship Examination.

THE following candidates, having passed the necessary examination, have been admitted Fellows of the College:—A. L. Fuller, M.R.C.S.Eng.; S. R. Godkin, L.R.C.S.I.; A. Greene, B.Ch.; M. R. J. Hayes, L.R.C.S.I.

The following have passed the Primary part of the examination:—K. Moinuddeen, L.A.H., L.R.C.S.I.; Miss M. M. S. Coghlan, M. Drummond, G. J. Fraser, H. M. E. H. M'Adoo, J. M'Mullin, H. H. Montgomery, Miss P. M. Powell, W. Prendiville, A. Stokes, and W. A. Swan.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

THE following candidates have passed the Final Examination, May, 1908:—S. Broderick, H. C. Burbidge, G. Collins, M. B. Dooley, E. Evans, F. N. Holden, G. S. Levis, F. W. Mathews, A. E. S. Martin, K. A. P. R. Murray, J. J. McGreal, D. O'Dwyer, M. Power, G. W. Stanley, J. F. Walsh.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ENGLISH AS IT IS HEARD.

"What! Assistance towards appendicitis!" exclaimed the Acton magistrate to-day, when a man asked him something.

"Pedlar's licence" was what the applicant had mumbled.—*Star*.

CLINIC.—Test papers for carrying about in the pocket are obtainable. Albumin, sugar, and reaction can be tested for by them. They are certainly useful. The only ones we know are those put up by the Roborat Co., 8, Harp Lane, London, E.C.

DR. A. G. B.—The report reached us as we were "at press." Too late for present issue.

THE LEMCO PRIZES.

As medical men will probably be in a better position to know the value of the Lemco extract, the Liebig Extract of Meat Company ask us to announce an interesting competition, the object of which is to find out how many uses there are for Lemco. Over 200 cash prizes are to be awarded, the first being £50. Competitors have nothing to collect, and no expense is involved. All that is necessary is to make out a list of the different ways Lemco is found of service, and to send it with one Lemco buff wrapper to Lemco, 4, Lloyd's Avenue, London. E.C. The best lists get the prizes. The closing date of the competition is June 15th.

PORTSMOUTH.—The gentleman who appears to be most entitled to credit for the rationalisation of military drill is Lieut.-Col. J. A. Davy, R.A.M.C. He worked for years to show the physiological faults entailed by the "pouter pigeon" chest in the military attitude of "attention," and his views have lately been adopted in high quarters, we understand.

A CORONER'S GRIEVANCE.

A North Country coroner arrived at an inquest very much perturbed. He was late, as he explained, because he had been misdirected when in search of a well-known chapel by a "silly woman."

"I have no end of trouble in finding these churches and chapels and vestries," exclaimed the Coroner. "If I have any more trouble I will go back to the old public-houses. Every man, woman, and child in the parish knows where the public-house is, but there's not one in twenty knows where the chapel is!"

[We have to thank a Sheffield correspondent for the foregoing.—ED.]

GLOUCESTER.—There was a typhoid patient at the farm which the suspected milk came from in the Kelvinside (Glasgow) outbreak, but the cause of that case and of the rest of the milk cases, is believed to be a healthy woman who had had typhoid sixteen years ago and still harboured typhoid bacilli.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MAY 27TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. H. L. Barnard: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. P. Stewart: Lesions of the Optic Chiasma.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Skin (Dr. Meachen); Eye (Mr. Brooks).

THURSDAY, MAY 28TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Sir Malcolm Morris: Seborrhœa of the Scalp.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical (Mr. Carson); X-Ray. 3 p.m.: Medical In-patient (Dr. Chappel). 4.30 p.m.: Demonstration of Clinical Methods of Estimating Blood Pressure (Dr. B. Price).

FRIDAY, MAY 29TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. E. Clarke: Clinique. (Eye.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. J. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

Appointments.

BARBER, A., M.B., B.S.Lond., Clinical Assistant to the Samaritan Free Hospital.

EDWARDS, HENRY JAMES, M.D.Durh., L.R.C.P., L.R.C.S.Edin., D.P.H.Lond., District Medical Officer by the Barnstaple (Devon) Board of Guardians.

FINZI, N. S., M.B.Lond., Honorary Radiographer to the Hospital for Epilepsy and Paralysis, Maida Vale.

FOTHERGILL, W. E., M.A., B.Sc., M.D., Lecturer in Clinical Obstetrics and Gynæcology in the University of Manchester.

HAMILTON, R., M.B., C.M.Glasg., D.P.H., Police Surgeon and Medical Officer of Health to the Burgh of Coatbridge.

JAMISON, REGINALD, M B., B.Ch.Oxon., Clinical Assistant to the Samaritan Free Hospital.

KEYWORTH, W. D., B.Ch.Cantab., Clinical Assistant to the Samaritan Free Hospital.

LEAKEY, A. B., M.B., Ch.B.Edin., Clinical Assistant to the Samaritan Free Hospital.

MANUEL, ALEXANDER, M.R.C.S., L.R.C.P.Lond., Clinical Assistant to the Samaritan Free Hospital.

OVERSBY, EDITH, M.B., Ch.B.Glasg., Medical Inspector of Schools for the county of Worcester.

PROCTOR, JOHN, M.B., Ch.B.Aberd., Clinical Assistant to the Samaritan Free Hospital.

RIPPON, C. S. U., M.B., B.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Tintern District of the county of Monmouth.

TEMPLE, GEORGE HENRY, M.B., C.M.Edin., Honorary Medical Officer to the Weston-super-Mare Creche.

Vacancies.

Lincoln General Dispensary.—Resident Junior Male Medical Officer. Salary, £175 per annum, with furnished apartments, fire, and lighting. Applications to the Secretary, 2, Bank Street, Lincoln.

City of Liverpool.—Education Committee.—School Medical Officer. Salary, £300 per annum. Applications to the Office of the Committee, 14, Sir Thomas Street, Liverpool.

Infirmary of the City of London Union.—Assistant Medical Superintendent. Salary, £150 per annum, together with furnished apartments at the Infirmary, rations, and washing. Applications to Edward R. Woodward, Clerk to the Guardians, No. 61, Bartholomew Close.

Bethlem Hospital.—Two Resident House Physicians. Apartments, complete board, and washing being provided, and an honorarium at the rate of £25 each per quarter will be paid. Applications to the Treasurer, Bridewell Hospital, New Bridge Street, E.C. (See Advt.)

Leicestershire and Rutland Asylum.—Junior Medical Officer. Salary, £130 per annum, with board, lodging, and washing. Applications to W. J. Freer, Esq., 10, New Street, Leicester.

Lambeth Workhouse.—Assistant Medical Officer. Salary, £125 per annum, with board, apartments, and washing at Renfrew Road Workhouse. Applications to James L. Goldspink, Clerk, Guardians' Board Room and Offices, Brook Street, Kennington Road, S.E.

Joint Counties Lunatic Asylum, Carmarthen.—Second Assistant Medical Officer. Salary, £160 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent, Joint Counties Asylum, Carmarthen.

Burnley Union.—Resident Assistant Medical Officer. Salary, £120 per annum, with furnished apartments, rations, washing, and attendance. Applications to J. S. Horn, Clerk, Union Offices, Burnley.

Births.

BLACKWELL.—On May 19th, at Oxshott Lodge, Oxshott, Surrey, the wife of T. C. Blackwell, M.D., of a son.

BROCK.—On May 19th, the wife of J. H. E. Brock, M.D., F.R.C.S., of 77, Fellows Road, South Hampstead, London, of a daughter.

BURRIDGE.—On May 22nd, at 13, Mackenzie Street, Slough, Bucks, the wife of John H. Burridge, M.R.C.S.Eng., of a son.

SHARPLES.—On May 5th, at 102, Lansdowne Road, Clapham, the wife of M. W. Sharples, M.B., of twin sons.

STAUNTON.—On May 19th, at Red Hill, Natal, the wife of G. P. Staunton, M.D. (*nee* Emily Jarrold)—a son.

Deaths.

DASHWOOD.—On May 19th, at Caistor Lodge, Bromley, Kent, Peyton Dashwood, aged 72, second son of the late Jarrett Dashwood, M.D., F.R.C.S.

MAY.—On May 21st, at 39, Oxford Gardens, London, W., Edward H. May, M.R.C.S., aged 73, late of 68, Pentonville Road, London.

VEALE.—On May 22nd, at Southern Hill, Reading, Deputy-Surgeon-General H. R. Veale, M.D., aged 76.

GLYCO-THYMOLINE TO THE NASAL CAVITIES

GLYCO-THYMOLINE

IS USED FOR CATARRHAL CONDITIONS OF
MUCOUS MEMBRANE IN ANY PART OF THE BODY

Nasal, Throat, Stomach, Intestinal
Rectal and Utero-Vaginal Catarrh

KRESS & OWEN COMPANY - 210 Fulton Street, New York

Sole Agents for Great Britain, THOS. CHRISTY & CO., 4—10 & 12 Old Swan Lane, London, E. C.

Examined and approved by the INSTITUTE OF HYGIENE, 34 Devonshire St., Harley St., W., where this preparation can be seen, and its properties and value can be explained.

Xeroform **Powder for wounds**; absolutely non-poisonous, non-irritant, sterilisable. Applied to **aseptic wounds** in a thick layer, Xeroform prevents the dressing adhering to the wound, the retention of discharge and suppuration along the path of the stitches. In **burns,** **intolerable** pain is at once relieved, healing is rapid with very little discharge, and the scar is smooth and delicate. A specific in **moist eczema** and in **chronic ulcers of the leg.**

Salit A rapidly curative remedy, relieving pain, in **rheumatic** troubles; to be rubbed into the skin in muscular rheumatism, acute neuralgia, teno-synovitis, rheumatic pleurisy. Salit is tolerated by the skin undiluted. No secondary actions.

Novargan Renders possible a **powerfully bactericidal treatment** of **gonorrhœa,** for, being non-irritant, it may be used in comparatively high concentration.

Ichthynate, Ammonium Ichthynatum, Heyden, chemically identical with ichthyol; very cheap.

Samples and Literature may be obtained of . .

SOLE AGENT FOR

CHEMISCHE FABRIK VON HEYDEN, Radebeul, near Dresden.

Dr. J. Collis Browne's

CHLORODYNE

THE ORIGINAL AND ONLY GENUINE.

From Symes & Co., Chemists, Medical Hall, Simla, January 5th, 1880.

To J. T. Davenport, Esq., London,

Dear Sir,—Have the goodness to furnish us with your best quotations for Dr. J. Collis Browne's Chlorodyne. We embrace this opportunity of congratulating you upon the widespread reputation this justly esteemed medicine has earned for itself, not only in Hindostan, but all over the East. The other brands are now relegated to the native bazaars, and judging from their sale, we fancy their sojourn there will be but evanescent. We could multiply instances *ad infinitum* of the extraordinary efficacy of Dr. Collis Browne's Chlorodyne in Diarrhœa and Dysentery, Spasms, Cramps, Neuralgia, the Vomiting of Pregnancy, and as a general sedative, that have occurred under our personal observation during many years. In Choleraic Diarrhœa, and even in the more terrible forms of Cholera itself, we have witnessed its surprisingly controlling power. We have never used any other form of this medicine than Collis Browne's from a firm conviction that it is decidedly the best, and also from a sense of duty we owe to the profession and the public, as we are of opinion that the substitution of any other than Collis Browne's is a deliberate breach of faith on the part of the chemist to prescriber and patient alike.

We are, Sir, faithfully yours, SYMES & CO.,

His Excellency the Viceroy's Chemists.

WHEN PRESCRIBING CHLORODYNE, REMEMBER TO ADD THE NAME OF "DR. J. COLLIS BROWNE," OTHERWISE A SUBSTITUTE MAY BE USED, TO THE DETRIMENT OF THE PATIENT.

Sole Manufacturers, J. T. DAVENPORT, Ltd., 117 Union St., London, S.E.

TRADE MARK.
A.D.1715.

An Adjuvant to, or Substitute for, the Mother's Milk.

The 'Allenburys' Foods.

THE "ALLENBURYS" MILK FOOD, on the addition of water as directed, forms an accurately estimated humanized milk, and may be given to the infant at the same time as the mother's milk. It has been proved by clinical experiments to be as easy of digestion as human milk. No digestive disturbance is caused by giving alternate feeds from the breast and the "Allenburys" Bottle. Weaning can therefore proceed gradually with comfort—both to mother and child. In addition to the above the "Allenburys" Milk Food No. 1 is free from all fermentive and pathogenic organisms. It is slightly alkaline as mother's milk, and has not suffered the acid decomposition which so usually affects cow's milk, and is the cause of much digestive and other trouble.

The "Allenburys" Malted Food No. 3
The third in the "Allenburys" series
"Allenburys" Milk Food No. 1
For the first 3 months

Cyllin Inhalant

as given off by the Cyllin Inhalator is most beneficial in all diseases of bacterial origin in the mucous lining of the throat, nose, and ears.

In Influenza

its germicidal action on the specific bacillus situated in the superficial layers of the mucous membrane of the respiratory tract, renders valuable assistance.

Cyllin is also put up as a Syrup, and in Capsule form (Palatinoids) for stomachic and intestinal antisepsis.

See pamphlet entitled "Standard Chemical Disinfectants." Copies, together with working samples, sent gratis and post free on applying to

Jeyes' Sanitary Compounds Company, Ltd.,
64, Cannon Street, London, E.C.

SCHERING'S MODERN THERAPEUTICS

EXODIN

Tasteless and Odourless Laxative, in Tablet form. Mild, but Sure and Safe.

EMPYROFORM

Dry, almost Odourless Tar Preparation. No Local Irritation or Intoxication. Excellent in treatment of Eczema, Psoriasis, etc.

SUBLAMIN

Non-irritant Sulphate of Mercuric Ethylendiamine Preparation for Hand Disinfection.

EUPHTHALMIN

Powerful Mydriatic. Excellent in Acute and Chronic Iritis. Far superior to all other Agents for Ophthalmoscopic Examinations.

BETA EUCAIN LACTATE

Local Anæsthetic par excellence. Soluble up to 20%. Toxic effects reduced to a minimum.

PIPERAZINE **PHENOCOLL** **CHLORALAMID** &c.

FOR SAMPLES AND LITERATURE APPLY TO

A. & M. Zimmermann,
3 LLOYD'S AVENUE,
London, E.C.

MODERN THERAPY

A Trustworthy Utero=ovarian tonic & sedative.

LIQUOR SEDANS (P., D. & Co.) has proved itself, through many years of continuous use by eminent gynæcologists in all parts of the world, a most efficient remedy in amenorrhœa, dysmenorrhœa, menorrhagia, acute or chronic inflammation of the womb and ovaries, threatened miscarriage, etc. It is often effectual in stubborn cases which have resisted other treatment.

Each fluid ounce represents :—

Viburnum Prunifolium (Black Haw)	60 grains.
Hydrastis (represented by Hydrastine) ...	60 grains.
Piscidia Piscipula (Jamaica Dogwood)	30 grains.
Aromatics	q s.

Dose :—½ to 1 fluid drachm in hot water several times daily.

SELECTIONS FROM CLINICAL REPORTS.

Disorders of Menstruation.

"Liquor Sedans is a useful tonic which can be given with iron or other preparations to those who are debilitated by excessive losses or suffering."

Edinburgh Medical Journal, July, 1900.

Endometritis.

"Milder cases of so-called endometritis often yielded to the administration during the week preceding the menses of the combination of hydrastis and viburnum prunifolium found in Liquor Sedans."

Glasgow Medical Journal, June, 1905.

Cancer of the Uterus.

"In the treatment of cancer which is beyond the stage for operative interference, Liquor Sedans is superior to opium. In my experience, it causes a considerable diminution and sometimes an absolute cessation of pain."

New York Lancet, June, 1901.

Various Pelvic Diseases.

Besides the clinical reports here quoted, others have appeared in various medical journals which show excellent results from Liquor Sedans in ovarian congestion, subinvolution, uterine engorgement, metrorrhagia, ovaritis, perimetritis, parametritis, etc.

Liquor Sedans is supplied in bottles containing 4, 8, 16, and 80 fl. ounces.
Soluble Elastic Capsules, each representing 1 fl. drachm of Liquor Sedans, are supplied in boxes of 12, 24, and 100.

Please specify "P., D. & Co." on all prescriptions.

PARKE, DAVIS & Co., LONDON.

BROMURAL (Knoll)

(α — Monobrom — iso — valerianyl — urea).

As regards its action, it occupies a position midway between the hypnotics on one hand and the bromides and valerian preparations on the other. It is a

HARMLESS, POWERFUL NERVE SEDATIVE AND MILD HYPNOTIC.

which causes no by or after-effects, and forms the preliminary for a short, healthy, dreamless sleep, from which the patient awakes fresh and invigorated.

DOSE:— as a sedative, - - - 5 grains several times a day.
as a hypnotic - - - 10 grains before bedtime.

KNOLL & CO., 8 Harp Lane, London, E.C.

MILO FOOD

Is based on Science and the Practical Experience of Thirty Years.
It is a Food with Milk as a basis.

By the simple addition of water in the proportion indicated in the instructions accompanying each tin, **MILO** adapts itself to children of various ages.

MILO

is much appreciated by nursing Mothers, and is invaluable at the time of weaning.

Awarded the Gold Medal at the Cape Town Exhibition, also the Certificate of Merit by the Institute of Hygiene, London.

Sample and pamphlet on "The Feeding and Care of Infants" sent free to Mothers and Nurses on application to

NESTLE & ANGLO - SWISS CONDENSED MILK CO., 6 & 8 Eastcheap, London, E.C.

VOL. CXXXVI. WEDNESDAY, JUNE 3, 1908. No. 23.

NOTES AND COMMENTS.

Habitual Criminals. THE Bill introduced by the Home Secretary in the House of Commons last week for the purpose of dealing with habitual criminals is one of the most noteworthy events of an eventful session. It marks a stage in the treatment of the criminal higher and more rational than any yet attained in this country, because it embodies for the first time the principle which has long been recognised by medical men that the habitual criminal is a mentally defective person, and must be treated as such. The levelling-up of prison conditions which has been in operation for the last twenty years has reached, or nearly reached, the maximum point to which it is safe to go; indeed, especially as regards dietary, we are not sure that the limits of wisdom have not been trespassed upon, as the diets provided for prisoners are now as good as those provided for paupers, and above the standard of living amongst the poorer members of the working classes. Now, although the reformatory effect of prison should be kept prominently in view, it is not safe nor prudent to lose sight of the deterrent effect, and if sentences are made too short and prison conditions too easy, there is no little danger that the wholesome dislike of incarceration which exists among the criminal classes will be much watered down. So long, at any rate, as the present Poor-law system prevails a substantial gulf should, and must, be fixed between the conditions of the workhouse and prison. Poverty is no crime, but if the surroundings of pauper life are much the same as those of prison life the temptation to avoid the former by risking the latter will make a strong appeal to the sporting instinct.

Permanent Detention. BUT Mr. Gladstone's new Bill makes a firm step away from the undue easing of the criminal's path, because it holds up before his eyes the prospect which he relishes least of all, namely, that of never being able to apply his skill and experience to their wonted uses, and leading perforce a virtuous existence. We fancy we are justified in saying that every atom of control of which he is capable will be exercised by the habitual criminal who recognises that a further transgression will lead to perpetual restraint from indulging in his wonted courses, and for those to whom crime is an instinct not to be resisted, the safeguarding of society and of themselves without undue rigour can only be the highest blessing. It is much to be hoped that the "humanitarians"—that is to say, those headstrong folk who oppose all disciplinary measures without regard to their merits—will not take into their heads to make trouble over this Bill. The habitual criminal, like the habitual inebriate, or the insane person, is not a responsible agent, and to deprive him of his liberty is just as much in his own interest as in that of society. The suggested safeguards against abuse seem to us to be adequate, and any aggrieved person should always be able to make a periodical appeal for reconsideration. The condition laid down is that the offences must be grave, and we trust that this will be interpreted to mean not poaching or petty pilfering, but chiefly grave offences against the person, especially sexual crimes. Persons convicted of unnatural offences of the latter order are very badly catered for at present, and this opportunity might be taken to make their restraint more equitable.

Medical Fees at Inquests. THE question of payments to medical men at Coroners' inquests has lately been before the Lancashire County Council, and that body has decided that the fee of a guinea for the post-mortem and a guinea for giving evidence is all that they are permitted to sanction for the medical witness, however long his journey may be, and however many times the inquest may be adjourned. As regards the latter point, their decision is unfortunately correct, but there is nothing to prevent the Council paying reasonable travelling expenses. There is no doubt that the whole of the procedure with regard to the Coroner and his court are antiquated in the extreme, and we should be very glad to see the whole subject taken up by the Government and put on a more modern basis. It is ridiculous that the guinea fee for the post-mortem should include all expenses with regard to analysis of the viscera, a long and complicated process, which alone should be paid for at ten times that figure. The omission specially to mention travelling expenses, is doubtless due to the fact that the Act enjoins that a neighbouring medical practitioner shall be called in, and it must press hardly on gentlemen who are so beloved of Coroners as to be frequently called from the North of London to the South to perform "expert" work which no one in South London is apparently capable of performing.

Merthyr School Children. THE Merthyr Education Authority and the good people of that district have been startled by the first report made to them by their recently-appointed medical inspector of schools. Dr. Askins, having examined the pupils, 283 in number, in three schools, found that 73 of them suffered from eye defects, 87 from diseases of the skin, 37 from diseases of the ear causing serious deafness; 57 from diseases of the throat and nose, 4 from diseases of the heart, 7 from mental deficiency, 3 from epilepsy, 4 from deformities, 1 from gastric ulcer, 7 from anæmia, 3 from diseases of the bladder, and 1 from rupture. Moreover, 95 per cent of the children had defective teeth, principally of the permanent set. These numbers are certainly very high, a good deal higher than those existing in most towns, and may well give cause for anxiety. The deafness especially, standing at 12 per cent, and being characterised as serious, is a grave factor. As these, the results of medical inspection begin to come in, there will doubtless be some confusion at first, especially as men and methods vary, but for purposes of comparison between the districts some more or less conventional standard will have to be fixed. But in any case we hope to hear that no districts are quite as bad as Merthyr.

Life Assurance and Fraud.

A point of much importance to medical men was before the Courts lately in an action brought by the executors of a lady against a well-known life assurance company to recover the amount, namely, £3,030, of a life policy issued by them. The lady had committed suicide, it appears, and the company denied liability on the ground that she had given a false answer to one of the medical examiner's questions. In answer to the interrogation, "Have you at any time had brain fever or any other disease of the brain?" she had replied, "No"; and after her death it came to the company's knowledge that she had suffered from acute mania seven years before she proposed to the office. She had not been certified, but had been a resident patient in a doctor's house, and it was said that the nature of her illness was never known to her. In the event the jury found that the lady had acted foolishly in not revealing the fact that she had consulted a medical man for what she believed to be a "nervous breakdown," but that she neither knew nor concealed the fact that she had been mentally deranged, and therefore there was no fraudulent concealment. Judgment was given for the defendants on condition that the premiums paid should be refunded. Medical examiners are aware how lightly many proposers for assurance reply to questions regarding their previous health and habits, knowing that as a rule it does not pay a company to refuse to honour a policy, and that the risk of any statement being disputed after death is extremely small. The result of this case should act as a healthy warning.

Licensing Dangers.

Objectors to the Government licensing proposals are bringing every imaginable species of argument to bear in opposition. Far be it from us to enter the thorny thicket of politics; all we have to say is that anything which reduces the amount of alcoholism in the country will, *ipso facto*, reduce enormously the amount of chronic disease. Whether the Government proposals will effect such reduction is a question for the individual judgment, but that there are grave auxiliary dangers to be faced if public drinking is curtailed is a matter of common knowledge among those who are acquainted with American medical literature. Hitherto this country has been happily free—or almost free—from one of the worst forms of quackery, namely, that of selling mixtures whose leading ingredient is alcohol, under the name of "Tonic medicines." By this dastardly trick the effect of temperance legislation is to a great extent thwarted and huge fortunes acquired by the vendors. The evil in America, especially in the prohibitionist States, has reached gigantic proportions, and the medical profession find it a most difficult one to tackle. This Government, therefore, will be well advised if they take this danger into account while there is time, and make adequate provision to meet it.

LEADING ARTICLES.

THE WAR AGAINST TUBERCULOSIS IN IRELAND.

The campaign against tuberculosis entered on a new phase last week with the opening of a depôt in Dublin for the sale of pasteurised milk. Our readers are aware of the strenuous work of Lady Aberdeen and her colleagues in the Women's National Health Association of Ireland, by which they have aroused in that conservative country a degree of interest never before felt in any sanitary question. The Tuberculosis Exhibition, first shown at the Irish International Exhibition in Dublin last autumn, has since visited practically every considerable town in the country, and everywhere it has gone it has attracted large numbers of intelligent spectators. The public lectures, given for the most part by medical men, have, in spite of some indiscretions, undoubtedly been of great value in educating the community to a knowledge, both of their responsibility and of their power with regard to the prevention of tubercular disease. That these efforts have not been without their result is shown by the large number of open windows one sees in the towns visited by the Exhibition, and by the greater activity shown by local bodies in exerting their powers of erecting sanatoria and otherwise dealing with the disease. Perhaps more significant than any other single fact is the activity displayed by the Local Government Board, the public department directly responsible for the control of sanitary administration in Ireland, and therefore for the neglect of public health in the past. In Dublin, not content with their educative efforts, the Health Association has entered on two definite lines of work. In conjunction with a committee of the physicians of the Dublin hospitals, they have inaugurated a scheme for visiting and assisting poor consumptive patients in their own homes. To consumptive patients presenting themselves for treatment at the out-patient departments of the hospitals cards are given. These cards, of which they may avail themselves if they choose, will obtain for them the visits and advice of a trained nurse employed by the Association. The duty of the nurse is to give advice as to the diet and mode of life of the patient, advice more definite and precise than can be given by the physician who does not see the patient in his own home. In cases where it seems required, sputum-flasks, clothing, and articles of food are supplied by the Association. Although only three months in operation, over one hundred patients have already come under the operation of the scheme. The other special task to which we have referred is the pasteurisation of milk. The entire expense of installation has been borne by Mr. Nathan Strauss, a wealthy American gentleman, who has made similar gifts to many other cities, and the plant has been erected under the supervision of Dr. Arthur Green, of New York, who has acted as the donor's expert adviser in similar undertakings elsewhere. The milk received in the depôt is drawn from a trustworthy dairy, in which the cows are subjected periodically to the tubercular test. The milk after pasteurisation is to be sold to the public. It will no doubt be a matter of satisfaction that the citizens of Dublin will find available a milk which will be above suspicion. Two things, however, will be necessary to render the depôt thoroughly useful—the sale of the milk at a low price, and such means of distribution as will bring it to the doors of the dwellers in the poorer quarters of the city. It is among them that milk-borne diseases are most rife, and it is for them that clean milk is most necessary. The schemes adopted by the Women's National Health Association seem to us well chosen, and we wish them every success. We confidently look for some reduction within the next few years of the appalling mortality from tubercle from which Ireland at present suffers.

SCARLET FEVER IN SURREY.

Dr. Seaton, Medical Officer of Health for the County of Surrey, has rendered good service to the branch of the profession he has made his own, by carrying out an inquiry into the incidence of scarlet fever during the last thirteen years in the district under his supervision. The results of the inquiry have been published in the form of a report. The question of the natural history of scarlet fever and the effect on it of compulsory notification and isolation, has been frequently brought forward by The Medical Press and Circular during the last four years, and although the lesson shown by articles in these columns—namely, that an enormous amount of money is being expended in hospital isolation with very little effect on the prevalence of the disease—was at one time scornfully rejected by authorities, it is now being appreciated. Dr. Seaton's report shows that 17,541 cases have occurred in the period under notice, but that the disease has been very mild and the mortality very small indeed, the number of deaths being less than those caused by measles. This paucity of deaths he attributes not to the decreased prevalence of scarlet fever, but to the benign form in which it now occurs. We do not follow Dr. Seaton in his deduction that this attenuation of virulence has been due to notification or isolation; first, because periods of benign scarlet fever always follow virulent outbursts; and, secondly, because, as he shows in his report, those districts which have not adopted hospital isolation have not suffered unduly in comparison with neighbouring areas where the plan is in force. Two of the faults which seem practically to nullify the influence of hospital isolation are shown to be "return" cases and late notification, and it seems rational to admit that if there were no return cases, and if early diagnosis could be made, *i.e.*, before the infective period, much good might, *primâ facie*, be expected from the system. The practical point is whether with these loopholes, which in the present state of our knowledge, it is impossible, or almost impossible, to close, it is worth while continuing to spend enormous sums in trying to "stamp out" a disease which causes so few deaths, when money cannot be found to deal with enormously important diseases like tuberculosis. In other words, would it not be a much better investment for the money available for disease isolation if it were expended on tuberculosis instead of on scarlet fever? We do not presume to say that the consumption sanatorium has been the success, or anything like the success, predicted for it, but to look at the matter from the humanitarian point of view alone, it seems to us that far more alleviation to human suffering would result from the hospital treatment of the consumptive who is very ill, and may even suffer terribly, than from cooping up for many weeks or months of numbers of healthy individuals who find the restraint irksome, and who seem to have little or no effect on the spread of scarlet fever. The only defence of the anomaly is that the scarlet fever isolation system is the established one, and possession is nine points of the law.

CURRENT TOPICS.

The Medical Defence Union.

The annual meeting at Liverpool last week of the Medical Defence Union registers the continued progress of its invaluable work. In face of the rapid growth of its membership from 400 in 1888 to over 7,000 in the present year, there is no need to insist upon the value of its protection to individual practitioners. As the President, Dr. Stamford Felce, pointed out, no class of the profession is exempt from the attacks of unscrupulous persons, and even consultants of the highest repute are occasionally obliged to defend themselves in actions for alleged negligence. We strongly advise any medical man who is not a member of one of the defence associations to write to Dr. Bateman, Trafalgar Square, London, for a copy of the last annual report. The record of the year's work forms the best testimony possible to the positive benefits conferred on members by this great professional organisation. As the oldest of these bodies, the Medical Defence Union has done pioneer work in establishing protective defence, and we are glad to see that now it is extending its operations againsts quacks and quackery. It is a sign of the times that at the Liverpool meeting a member formally called the attention of the Union to the prescribing and medical practice of chemists.

University Professors and Religious Tests.

We cannot forbear expressing our regret that Mr. Birrell, in defiance, as he admits, of his better judgment, has consented to insert a clause in the Irish Universities Bill, imposing tests on the professors of the colleges of the new university. The test will probably resemble that at present in force in the Queen's Colleges, namely, a declaration on the part of the professor that he will not teach anything contrary to the faith of his students. This declaration may lead to serious trouble in the future, since the tenure of office of the professors is to depend on the will of the governing body of the colleges. In the case of scientific teachers this concession of Mr. Birrell is not unlikely to hamper teaching in a disastrous fashion. We do not suggest that there is any fundamental hostility, or even incongruity between science and religion, since two truths cannot clash, but the ecclesiastical view of truth does not always agree with the scientific. If, as seems likely, the ecclesiastical element will be strong in the new governing bodies, it may go hard with men of science. Imagine the mercy shown to a Tyndall or a Huxley in the new universities! But our objection is based on broader grounds. Science and learning should be free and untrammelled. The teacher and the investigator must be left free to teach and to say, regardless of the opinions of others, the truth as he knows it, and any attempt to shut his mouth by the imposition of tests is alike immoral and unscientific.

The Council of the Royal College of Surgeons of England.

The annual election of members to the Council of the Royal College of Surgeons, England, takes place on the 2nd proximo, at which no fewer than four vacancies will be competed for. These are created by the resignation of Professor Howard Marsh, and Messrs. Harrison Cripps, J. Ward Cousins, and A. Pearce Gould. Professor Marsh, now the Master of Downing College, Cambridge, has resigned in consequence of the pursuance by the majority of the Council of a policy which does not meet with his acceptance. The other three councillors retire by rotation, and, presumably, they will offer themselves for re-election. There is one prominent representative of the surgical branch of our art, who, we believe, has never offered himself for election to the Council. We allude to Sir Victor Horsley, than whom, it might rightly be said, no one could be more fitted for the honour. Surely, despite all his professional and medico-political duties, Sir Victor might be prevailed upon to enter the Council —for it goes without saying that his election would be assured. If he agreed to this proposition, in time, undoubtedly, the high honour of being President of the College would naturally fall to him, which would only be some return for the progressive and original work which he has accomplished in surgical science and medical politics.

The Examinations of the Apothecaries' Hall, Dublin.

It will be seen in our report of the proceedings of the General Medical Council that the Executive Committee of the Council have recommended that the examiners appointed by the Council to examine in surgery at the qualifying examinations of the Apothecaries' Hall, should be instructed to supervise the medical and obstetrical portions of the examination, with the object of securing that at each qualifying examination the required standard of proficiency is maintained. The representative of the Apothecaries' Hall on the Council, Dr. Adye Curran, strongly objected to this proposal, and even called attention to the necessity, if it was adopted by the Council, of seeking a remedy elsewhere. Under the circumstances, therefore, we do not propose to comment on the necessity or otherwise for such an inspection, but we do desire to point out that even if the principle of supervision is accepted, surgical examiners are hardly the proper persons to supervise examinations in medicine and obstetrics. Supposing under such circumstances the Apothecaries' Hall carried out their threat of appealing to the Courts for protection, we fancy the General Medical Council would not improve their position by having to admit that they had appointed as supervisers of an examination in obstetrics, gentlemen who probably had not seen or attended a case of labour since their student days. It is obvious that if such supervision is necessary, the proper persons to supervise the medical and obstetrical portions of the examinations are men who devote their time to the practice of these branches of the profession.

The Irish Universities Bill.

The Irish Universities Bill is dragging along in the Committee stage, and at the present rate of progress is likely to continue so doing for a considerable time. At the end of last week the first clause had been passed, and the second clause was under discussion. In the meantime, an unforeseen cloud has arisen in the proposal by Mr. Birrell to affiliate Magee College to the Belfast University, and Maynooth College to the Dublin University. The effect of this is twofold. In the first place, it places in the power of extern students, resident and taught in ecclesiastical seminaries, and out of touch with University life, to swamp in Convocation the electoral power of graduates who genuinely belong to the University. In the next place, it obviously, and for all time, brands the University of Belfast as a Presbyterian institution and the new University in Dublin as a Roman Catholic institution, and thus at once sweeps away all suggestions that such is not the case. It is obvious that the first of these two consequences, at any rate, is a very serious matter, as when taken in conjunction with the excessive representation of local bodies on the Senates of the Universities, it goes far to destroy any prospect there was that the Universities should be governed by an academic body. Another sensation is to be found in a letter to the press by Mr. Campbell, the junior Member of Parliament for Dublin University, in which he points out that the University of Dublin is bound to suffer very severely under the provisions of the new Bill; that there is no really representative opinion in Ulster in favour of the establishment of a University in Belfast; and that, under the circumstances, the best thing that could happen would be the union with, or the affiliation of, the Queen's College, Belfast, to Dublin University. The terms of such a union, he thinks, would doubtless be difficult to adjust, but not impossible. If such a union were to take place it would only be an additional proof that in Ireland, as in Africa, the unexpected has a way of happening.

A Cingalese Quack at the Franco-British Exhibition.

The Franco-British Exhibition contains an excellent illustration of the modern quack, of the kind that figures largely in every modern scheme of civilisation. The gentleman in question is a diminutive Cingalese medicine-man, four feet in height, who is to be consulted in the Cingalese village. The fact that he does not speak English will probably not abate one jot the confidence of his clients in his medical skill. His great field is said to be in the cure of "sprains," a sphere of activity that is peculiarly inviting to the quacks of all nations and all climes. Gout and rheumatism he apparently claims to be able to treat, although it seems curious that a Cingalese should have acquired any close acquaintance with those home diseases. As to indigestion, he is said to possess many remedies of great value, and here, again, the claim is more than reminiscent of the shoal of quack advertisements of a thousand-and-one vaunted specifics for the cure of dyspepsia. It says little for the intelligence of mankind when a native of a remote Asiatic village is imported into the centre of the richest and most enlightened civilisation in the world in order to offer remedies for its disordered digestion. Nor does it say much for the preceding army of quacks who, despite their claims to omnipotence in that special branch of therapeutics, have left any uncured dyspeptics behind for the Cingalee to practice upon. The medicine-man, it is said, understands one English word, to wit, "stethoscope." Its mention within his hearing arouses, so we gather, a sort of fury, on the ground that "plants and herbs" cure more than stethoscopes. His practice appears to be no better and no worse than that of the myriad quacks who batten upon the credulity of mankind in all parts of the world, civilised and uncivilised. The present writer has seen a quack advertisement pasted on the walls of a Chinese town!

Medical Euphemisms.

The exigencies of medical practice oblige one to resort to various verbal subterfuges in order that the truth may not be brought too clearly home to the patient on the one hand, yet may convey an unmistakable meaning to the ears for which they are intended. The use of the word "specific" is a very good example of the kind, and "neoplasm" is another. Of late a tendency has manifested itself to discuss certain medico-social questions more openly than was formerly held to be admissible, and a new vocabulary has become necessary in order to avoid shocking the feelings of ladies bent on reform, who while willing, nay, anxious, to discuss the social questions still squirm at the descriptive term. In France, Brieux's celebrated play, "Les Avariés," *e.g.*, "the Damaged Ones," has called public attention to the immense amount of evil that is inflicted on a defenceless section of the public by unscruplous, careless, or ignorant men, and parents are now beginning to inquire closely into the medical history of the candidate sons-in-law in order not to ally themselves with an *avarié*. In order to permit the subject being discussed in the bosoms of families, the quasi-medical terms, "avariosos" and "neisserosis" have been introduced to designate syphilis and gonorrhœa, and bid fair to become acclimatised.

PERSONAL.

The Earl of Lytton presided on May 26th at the annual meeting of the State Children's Association.

The French Hospital, in Shaftesbury Avenue, was visited last week by M. Fallières.

Dr. G. Nixon Biggs has been appointed Assistant Surgeon to the Ear, Nose, and Throat Department of the Dreadnought Hospital, Greenwich.

Lord Cromer will take the chair at the first meeting of the Research Defence Society, to be held at 20, Hanover Square, on June 19th, at 5 p.m.

Dr. Samuel Rotmann, who, although a Jew, has spent twenty-eight years as a surgeon in the Russian Army, has now retired from active service.

Dr. J. B. H. Davson, Medical Officer, Sierra Leone, has been transferred to the Gold Coast Colony on promotion, as Senior Medical Officer of that Colony.

Dr. Raymond, the well-known French neurologist, will deliver an address at the Royal College of Physicians of London, on June 22nd, at 5 p.m. His subject will be: "Les Maladies dites Familiales."

Dr. J. B. Addison who, since the transfer of Dr. R. Denman to the Federated Malay States, has been acting as Chief Medical Officer, Seychelles, has been confirmed in that office.

A statue to Queen Alexandra has recently been erected in the grounds of the London Hospital. It is executed in bronze by Mr. George Wade, R.A., and shows her Majesty in Coronation robes.

Dr. Comyns Berkeley, B.A., M.B. Cantab., M.R.C.P., has been elected Obstetric Physician, and Dr. W. F. Victor Bonney, M.S., B.Sc., F.R.C.S., Assistant Obstetric Physician, to the Middlesex Hospital.

At the General Hospital, Stratford-upon-Avon, on May 20th, Dr. H. Lupton's long and valuable services to the institution were recognised by the presentation to him of a handsome silver tea and coffee service and silver salver.

Earl Cawdor, the treasurer of the London Homœopathic Hospital, Great Ormond Street, W.C., has received the sum of 1,000 guineas for the endowment of a bed in the new extension, in memory of Dr. George Napoleon Epps, from his daughters and sons.

Dr. M. Armand Ruffer, C.M.G., M.D.Oxon., President of the Maritime, Sanitary, and Quarantine Council of Egypt, has been granted the Royal permission to wear the insignia of Commander of the Order of the Crown of Italy, conferred on him for his valuable services by H.M. the King of Italy.

After a considerable period of ill-health, the secretary of University College Hospital, Mr. Newton H. Nixon, has found himself unable to resume the duties of his post, and has in consequence retired. He has been granted a substantial pension by the hospital authorities.

The Clarence Wing fête, held at St. Mary's Hospital last week, has enriched the opening fund to the extent of some £2,000. This sum resulted from the sales alone, and it is hoped that the subscription list in conection with the fête will be considerably more productive.

At the Samaritan Free Hospital Mr. Butler-Smythe, F.R.C.S.Ed., and Dr. Corrie Keep, M.D., have been promoted from the out-patient department to be surgeons to in-patients. The vacancy on the junior staff has been filled by the appointment of Dr. R. D. Maxwell, M.D., F.R.C.S., to be surgeon to the out-patient department.

Mr. W. P. H. Montgomery, honorary assistant surgeon to the Manchester Royal Infirmary, who has been in close association with the Infirmary for about 20 years, has written from Bournemouth regretting that, owing to ill-health, the time had come for him to resign his position.

A CLINICAL LECTURE

ON

INFANTILE MARASMUS. (a)

By G. F. STILL, M.A., M.D., F.R.C.P.,

Professor of Diseases of Children, King's College, London; Physician for Diseases of Children, King's College Hospital; Physician to Out-Patients, Hospital for Sick Children, Great Ormond Street.

GENTLEMEN,—Marasmus, or wasting, is a symptom rather than a disease, and, like most symptoms, may have many different causes. I mention this at the outset because I think there is a tendency to jump to the conclusion that whenever an infant is wasting, there must be something wrong in the food, and that all that is required is to change the food, and keep on changing it until the weight begins to rise. Undoubtedly digestive trouble from unsuitable feeding is the commonest cause of wasting in infancy, but even so, it does not follow that the food requires changing; it may be that the fault is not in the food, but in the manner of feeding, particularly as to the frequency or the bulk of feeds; moreover, there are cases in which the wasting is not due to any fault in the food or manner of feeding, but to some cause in the infant, such as chronic constipation or congenital syphilis.

Unsuitable food—to deal with the commonest cause first—is not necessarily, or even usually, grossly improper food; it is unsuitable usually through some slight excess or deficiency in one or other of the constituents of an ordinary milk mixture.

Faults in the Food.—Insufficient dilution is a common fault. An infant who is fed with equal parts of milk and water at a month old, or with two parts of milk to one of water at three months, is likely to have a disordered digestion and waste; it is perfectly true that there are infants who will thrive on undiluted milk almost from birth, but in my experience this has been the exception, not the rule. One may accept as a sort of working standard the following proportions:—

Three months, milk and water equal parts.
Six months, milk 2 parts, water 1 part.
Nine months, milk 3 parts, water 1 part.

Any considerable departure from these proportions is likely to result in failure of nutrition, except in cases where cream is added, and where, therefore, the dilution may be much greater without harm.

An excessive proportion of cream is often responsible for nutritional disturbance. An infant may tolerate an average proportion of 4 per cent. of fat in human milk, but my own clinical observation has convinced me that the cream from cow's milk is less easily tolerated, and that it is seldom wise to exceed 3.5 per cent. of fat in the mixture, whilst there are many infants who cannot digest a mixture containing more than 3 per cent. of fat. Often I find that a wasted infant has been given two tablespoonsful of cream in a feed of three ounces, consisting of equal parts of milk and water; no attempt has been made to ascertain the strength of the cream, which proves to be the ordinary 48 per cent. cream as usually sold in London. The percentage of the fat in the mixture is therefore 5-6 per cent., and after gaining weight rapidly for a time on this mixture the infant has begun to waste. Herein lies the importance of a practical working knowledge of the composition of milk and of the ordinary foods in common use for infant feeding. Percentage analysis may be, and often is, a very incomplete guide to the choice of a food, but it gives, at any rate, one means by which we may compare any food with the ideal standard, human milk, and with the standards of artificial feeding which experience has shown to be most generally successful. Nature is lenient in her requirements, exacting no slavish adherence to decimal points of percentage, as some would have us believe, yet there are fairly-defined limits of variation which must be observed if an infant is to thrive. To give an infant a food which contains less than 2 per cent. of fat for any considerable length of time after the age of three months is to incur the risk of rickets; on the other hand, to give a food containing 5 per cent. of fat or more is to expose the infant to risk of gradual failure of assimilation, if not to acute digestive disorder.

So, too, with the sugar—any excess is likely sooner or later to bring flatulence and discomfort, with loose, slimy stools and wasting. It is remarkable how little sugar seems to be necessary, but nutrition is likely to be poor when the sugar percentage falls far below 5 per cent., while, on the other hand, sugar above 8 or 9 per cent. is very apt to cause digestive disturbance. In the proportion of sugar is to be included any other carbohydrate present, whether insoluble as starch, or soluble. In my opinion, starch should not enter at all into the diet of an infant under nine months of age; even the small proportion present when barley-water is used as a diluent—that is, .5-1 per cent. of starch at most, will sometimes cause definite disturbance of digestion.

Condensed milk is responsible for much infantile marasmus in hospital practice; and this is usually not due to any excess of sugar, but to excessive dilution. An extreme instance was that of a wasted baby to whom Nestlé's milk was being given in the proportion of four teaspoonsful to two pints of water, which would yield a mixture containing at most: proteid .5 per cent., fat .7 per cent, sugar 2.75 per cent; in other words, practically nothing more than a weak solution of sugar. Even when diluted most carefully so that the proportions become: proteid 1.1 per cent., fat 1.2 per cent., sugar 6.7 per cent, it is so deficient in fat that it is quite unsuitable for prolonged use in infant feeding.

Fresh cow's milk, it is to be remembered, can be made almost as unsuitable as condensed milk if it is diluted too much. I see infants sometimes who, at the age of six or eight months, are having equal parts of milk and water, or, as more often happens, barley-water, with no addition of cream. The result is poor nutrition and rickets.

Faults in the Manner of Feeding.—The manner of feeding is often more responsible than the food for wasting in infancy. Even with breast-feeding, irregularity in the intervals may be sufficient to disturb digestion and produce wasting; so, too, does feeding "whenever he cries," which generally means that the infant is taking milk almost every hour. It is always a wonder to me how mothers who know well enough that if they themselves took meals at short and long intervals quite haphazard they would suffer very quickly with indigestion, expect their babies, whose digestion is so much more easily upset, to digest and thrive when they are fed in this irregular manner.

(a) A Lecture delivered at the Medical Graduates' College and Polyclinic, London, May 12th, 1908.

Even with regularity, the intervals may be wrong; the infant is rarely fed too seldom, usually feeding is too frequent; to feed an infant at three months with three or four ounces every two hours is to overtax digestion and induce marasmus.

Another cause of marasmus upon which I wish to lay some stress—for it is, I think, not generally recognised—is the use of feeds too large for the age. An infant is given two ounces when he is a fortnight old, and perhaps five or six ounces when he is three months old. Now, what happens? At first he gains weight rapidly, and at three or four months old he is a theme of admiration, his weight is considerably above the average, and everything seems *couleur de rose*. Then comes a pause, the weight begins to fall, and soon the infant is in a state of marasmus, from which it is exceedingly difficult to extricate him. I regard these cases of marasmus from too large feeds as some of the most difficult to treat.

Causes in the Infant.—If ever marasmus can be called a disease rather than a symptom it is in a certain group of cases in which, in spite of the best of feeding—it may be breast-feeding—the infant begins to waste and goes steadily downhill, with no evidence of digestive disturbance. Such a condition sometimes occurs in successive children in the same family.

For these cases we have no satisfactory explanation; it seems, indeed, as if, like "the wonderful one-hoss shay," the assimilation in these infants comes to the end of its term of activity before the rest of the functions of the body; it is endowed *ab initio* with less than the ordinary share of durability.

Possibly the fact that some infants manifest from the beginning an extraordinary idiosyncrasy in the digestion of one or other food constituent, so that one infant can digest only the minutest proportion of fat, another only a very low percentage of sugar, and another very little proteid, may explain some of these cases of marasmus starting from birth, for it is evident that if the idiosyncrasy included any two of the constituents, nutrition would be extremely difficult, if not impossible.

A very common group of cases is that in which marasmus follows some acute gastro-intestinal disturbance, especially diarrhœa. Some of these cases resist all treatment, and possibly the theory that fibrotic changes in the mucosa have destroyed the absorptive surface or large areas in the intestine may account for the difficulty in improving nutrition; but probably in many there is nothing more than a disorder of function—an intestinal dyspepsia.

Congenital syphilis is a more easily overlooked cause of marasmus than might be imagined. The marasmus may occur before any other manifestations of the disease are present, so that a diagnosis of the cause may be impossible unless the parents are able to supply the necessary information; and it is very important that they should, for although some of these cases do not respond at all to antisyphilitic treatment, in others mercury at once improves nutrition and saves the infant's life.

There is one cause of marasmus to which I wish to draw special attention, for it is often ignored, namely, chronic constipation. It may be quite useless—nay, worse than useless—to try food after food in the hope of hitting upon the food which will "suit the child," when the one thing needful is regular administration of some laxative drug. Even when the feeding is at fault, constipation will aggravate the difficulty of nutrition; and a regular dose of grey-powder twice or three times daily will often secure a good result from changes in the feed, which otherwise might be made in vain.

Another condition which profoundly affects the nutrition of an infant is congenital heart disease. The blue child, with its clubbed fingers and cyanotic cheeks, excites no surprise when it fails to gain weight; but, remember that congenital heart disease is often associated with no cyanosis whatever, and that in these cases, where there is nothing to draw attention specially to the heart, failure to gain weight or actual loss of weight is a frequent manifestation. I have seen many such cases in which the infant had been under treatment for wasting; there was nothing to call attention to the heart, and it had been assumed that the food was at fault; first one food was tried and then another, but still the infant failed to thrive. Examination showed signs of congenital heart disease. Unfortunately, the recognition of this does not help us in therapeutics, but it does help us I think, in other ways. In the first place, it is no small thing to know the cause of any symptom that we are called upon to treat; such knowledge gives confidence to the doctor, and the knowledge that the doctor knows what he is dealing with gives confidence to the parents. It is far more satisfactory to be able to say to the parents, "The wasting in your baby is not due merely to indigestion or to lack of suitable food; it depends largely upon the deformity of the heart," than to try food after food with unexplained failure, while the parents are disappointed and dissatisfied at what they suppose to be the doctor's lack of skill in "hitting off" the particular food required. In the second place, recognition of congenital heart disease as a cause of marasmus will prevent the hasty assumption that because an infant is not thriving the food must at once be changed. I have known an infant weaned by the unskilled advice of a nurse, when its poor nutrition was in reality due, not to unsuitability of the breast milk, but to congenital heart disease. I suppose that weaning in such a case was the worst possible step which could have been taken. I have not mentioned tuberculosis hitherto, because it must occupy a place in the background of the clinical picture of infantile marasmus. Tuberculosis is extremely rare under three months, rare under six months, and only begins to be common towards the end of the first year. The sooner the term "consumptive bowels" is dropped the better, for it too often confers upon the results of improper or careless feeding the dignity of a dispensation of Providence.

Treatment.—The treatment of infantile marasmus embraces the whole subject of infantile feeding, upon which I cannot enter now, but I will say generally that where marasmus is due to digestive disorder, a weak food is commonly the right food; it is often wise to start afresh with veal broth only or chicken broth, to which milk-sugar may be added in the proportion of a teaspoonful to every 3 ounces. After a day or two milk, freely diluted and peptonised, may be substituted for the broth at alternate feeds; a more readily-assimilable food where even weak peptonised cow's milk cannot be assimiliated is asses' milk; it is often remarkable how well a feeble marasmic infant will thrive for a time on asses' milk. Where asses' milk is impracticable on account of expense, one of the various brands of desiccated milk often succeeds, and in any case may be useful as a temporary food when it is decided to try something a little stronger than asses' milk or much-diluted cow's milk. Where fresh cow's milk in various dilutions has already failed, it is often best to proceed at once to fully-peptonised milk.

Fats are very commonly ill-tolerated by the marasmic infant; the addition of cream is, therefore, often best avoided altogether, and, if used, it should be given in very small quantities. For the same reason cod-liver oil is often quite unsuitable for a wasted infant; it retards digestion and aggravates the trouble.

Lastly, in connection with the diet, I would insist upon the need for slowness in increasing the strength of the food. Again and again the medical man is over-persuaded by an anxious mother into increasing the food or the strength of the milk-mixture, and the result is a most disheartening loss of weight instead of improvement of nutrition.

In treating these infants, remember that for a feeble, wasted infant *warmth* is of the greatest importance. In these days when open-air treatment is the fashion, it is necessary to point out that warmth is far more important to an infant than open-air. By all means let the infant have plenty of fresh air, but see that it is warm fresh air if the infant is in a puny, marasmic state; the excellent results of the incubator, with its temperature of 80°-90° and its meagre supply of fresh air, demonstrate sufficiently the importance of warmth.

With regard to drugs, malt is far more useful for these wasting infants than cod-liver oil; sometimes by using malt instead of ordinary sugar to sweeten the food a distinct improvement in weight is obtained.

Some very interesting observations have recently been made by Dr. Simpson, of Edinburgh, upon the effect of thyroid extract on infantile marasmus. He found that the administration of doses of $\frac{1}{3}$-$\frac{1}{2}$ grain of this drug (Burroughs Wellcome's tabloids were used) three times a day was sometimes followed by more or less steady rise of weight.

I have had some cases under my care at hospital in which it certainly seemed as if a gain of weight was started by the administration of thyroid. I have used the Thyroideum siccum of the British Pharmacopœia in doses of 1-15th to 1-10th grain once or twice daily.

Lastly, I should like to refer to inunction of oil, which is an old-fashioned practice, and, as far as I know, not open to any objection, apart from its "messiness" and unpleasant smell, which, however, may be overcome to some extent by using neat's-foot oil instead of cod-liver oil. I have never been able to satisfy myself that any oil is absorbed through the skin in these cases, but I doubt not that it helps to maintain the warmth of the infant, and in this way may be of value.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Wm. St. Clair Symmers, M.B., C.M. Aberd., Professor of Pathology, Queen's College, Belfast. Subject: "Some Landmarks in the Study of Tuberculosis."*

ORIGINAL PAPERS.

THE MILK PROBLEM,
OR THE
PRODUCTION AND DISTRIBUTION OF PURE, CLEAN MILK. (a)

By JOHN C. THRESH, D.Sc.Lond., M.D., D.P.H. Camb.,

Lecturer on Public Health, London Hospital; Examiner in Hygiene, University of London.

One of the most important—or, I may venture to say, *the* most important article of diet for children (and for invalids) is milk, and for this reason no apology is necessary for my selecting it as the subject of a popular address.

Why milk takes this high rank as an article of food is well known to most of you. It must suffice, therefore, if I merely state that it is the one natural article of diet which contains all the necessary constituents for growth and nutrition, and for the formation of blood, bone and muscle. Not only so, but it contains these in such a proportion that, by slight modification, it may be made suitable for children of any age. Mothers' milk is the natural food for the infant until it is some months old, and, whenever possible, this should be its only food. The milk of no animal can be modified so as to make it identical with mothers' milk, and a mother who can suckle her child and refuses to do so fails in her duty to her offspring, and in her duty to the community, and the sin of omission on the part of the parent is often visited upon her children for more than one generation.

Milk is a product of living tissues, a vital fluid, which, the chemist tells us, contains proteids or flesh-forming matters, sugars, fats, etc., all forming an emulsion in water; but the physiologist tells us that it contains other constituents of great importance, substances of such complex constitution that the application of heat or the addition of chemicals easily destroy them and diminish the value of the milk as a food.

Containing all the necessary elements of nutrition constitutes its great value as a food, and at the same time constitutes its great danger if it is not pure. It is not only the ideal food for animals, but it is the ideal food for bacteria, those very lowest forms of life, some of which are the scourge of the human race.

Put a few bacteria into a little warm milk, and in a few hours they will have increased to millions. Some of those which thrive well are, unfortunately, those which can produce disease when introduced into the human system. The case is very different with water. When the disease-producing bacteria are introduced into water, they die out with greater or less rapidity, they rarely, if ever, multiply. Hence the great importance of keeping them out of the milk. If any water contained in one gallon as many bacteria as may be contained in one or two drops of dirty milk, it would be condemned as utterly unfit for drinking purposes. Yet we have systematic bacteriological examinations made of our water supplies, but we rarely hear of such examinations being made of our milk supplies.

Milk taken in the most careful manner and under the best conditions contains a considerable number of bacteria; but if the milk is properly cooled (to about 40° F.) it will keep for 48 hours with but little change. At 50° F. there will be a most marked increase in 48 hours, but at 70° F. the bacteria will have increased so enormously that a single drop will contain as many bacteria as there are human beings on the globe.

Fresh Milk.		Milk after keeping 48 hours.		
Bacteria per c.c.	...	at 40° F.	at 50° F.	at 70° F.
2,400		3,600	540,000	25,000,000,000

Very fortunately for us, nearly all these bacteria are harmless, if they are not present in such number as to have altered the character of the milk; and fortunate again is the fact that fresh milk has a marked germicidal action.

How do these bacteria get into the milk? As I have stated, some are present in the most carefully drawn milk. Probably these come from the teats, the milkers' hands, the dust from the cows' hide, and the dust in the air. But in milk from unhealthy cows they may come from the milk glands themselves, and in milk, as usually produced, they come chiefly from the manure which coats the flank of the cows, and which all too often is found on the udders also. Sometimes they are also derived from impure water used in washing the utensils, and from the hands or throat of a milkman who may possibly be suffering from an infectious disease.

The bacteria we have most to dread are those producing diarrhœa (possibly the bacillus enteritidis of Gaertner), the bacillus of tuberculosis, causing the various forms of consumption; the bacillus of typhoid fever and bacillus of diphtheria, and the still smaller organisms which cause scarlet fever and epidemics of sore throat.

(a) Abstract of paper read before the Birmingham Branch of the Incorporated Institute of Hygiene, March 30th, 1908.

I have recently had to examine a good many samples of milk, and I have made sketches of the various kinds of dirt, etc., which I found in some of them. These sketches I will pass round for you to examine. Bacteria you will find in all, sometimes in masses of millions, and in all you will find *débris* which could only have been derived from manure. In clean milk the amount of deposit obtained from one pint is exceedingly small in amount, and of a pale fawn colour. In dirty milk it is much more abundant, and of a dirty brown colour. The centrifugalised deposit from pure milk, when injected into a guinea-pig, has little, if any, effect upon it, but the residue from a dirty milk causes the death of the animal.

My experience is no unusual one. The Medical Officer of Health for the City of London caused a number of samples of milk to be examined annually, and the following results are taken from his report:—

	1904	1905	1906	1907
Fairly clean and pure	48·8	68·2	80	54·2
Unclean	43·6	22·7	12	37·5
Tuberculous	7·7	9·1	6	8·3

In this city (Birmingham) last year it was found that 14 per cent. of the samples of milk which came into the city from outside contained tubercle bacilli, and in Liverpool the average for the last six years was 14.5 per cent. Similar results have been obtained in Manchester and elsewhere. We may take it, therefore, that fully 10 per cent. of the milk used at the present time is tuberculous, and capable of producing tubercular disease in children, if not in adults, and that another 30 to 40 per cent. is so unclean as to be dangerous to health, especially in summer time, when the bacteria increase most rapidly.

To enable us to realise the importance of the milk problem, we must first consider to what extent the impurities in milk affect the health.

Tuberculosis of the lungs is a cause of death which is steadily and continuously declining, and to a far greater extent than other forms of tuberculosis which chiefly affect children. Milk may not be the sole cause of these forms of tuberculosis, but we have two very significant facts which, taken together, tend to show that there is some connection between them:—(1) Cows' milk is the most important food of young children. (2) Cows' milk frequently contains the germs of tuberculosis. The results of the researches of the Departmental Committee which issued a report last year lead the members of the Committee to report as follows:—

"There can be no doubt that a certain number of cases of tuberculosis occurring in the human subject, especially in children, is the direct result of the introduction into the human body of the bacillus of bovine tuberculosis, and there can also be no doubt that in the majority of these cases the bacillus is introduced through cows' milk. Cows' milk containing bovine tubercle bacilli is clearly a cause of tuberculosis and of fatal tuberculosis in man."

Whilst referring to this report, I may make one other quotation:—"A very considerable amount of disease and loss of life, especially among the young, must be attributed to the consumption of cows' milk containing tubercle bacilli. The milk coming from such a cow (*i.e.*, one suffering from tuberculosis, and which may be yielding tuberculous milk), ought not to be used as food at all."

Other forms of tubercular disease (general tuberculosis, scrofula, lupus and tuberculous affections of the bones, joints, and other parts of the body not especially specified), the Registrar-General states, cause an average mortality of 186 per million population, or over 5,000 per year in England. "The mortality from these diseases differs from that of the other specified forms of this infection, in that it has risen considerably in the course of the last 40 years, more especially among children under five, whose mortality has increased since 1871-80 by 81 per cent."

That illness may be caused by milk injected with the germs of typhoid fever, diphtheria, and scarlet fever is well known to every medical man. Besides these, many outbreaks have occurred of anomalous illness, sometimes fatal in character, and usually characterised by feverishness and sore throat, due to milk infected with purulent matter from the udders of diseased cows.

Every year epidemics of infectious disease of a more or less serious character, and due to milk, are recorded, and many more, judging from my own experience, pass unrecorded, or are only referred to in the reports of Medical Officers of Health, and there are good reasons for believing that infantile diarrhœa is in some way related to the milk supply.

Dr. Savage, the Medical Officer of Health for Colchester, found that only 26 per cent. of the infants of the borough were hand-fed; yet, amongst these children, 82 per cent. of the fatal cases of diarrhœa occurred.

At East Ham Dr. Sowden found that 80 per cent. of the children were breast-fed; yet only 5 per cent. of the diarrhœal deaths occurred amongst such children. Fresh cows' milk formed the diet of 38 per cent., and condensed milk of 39 per cent. of the children who died from diarrhœa.

That these are not unusual results may be gathered from the fact that Dr. Hope has stated that in Liverpool the deaths from diarrhœa in children under six months of age were in the following proportion:—Breast-fed, 1; partly breast-fed, 15; no breast feeding, 22.

That milk forms the chief vehicle of infection there can be no doubt, and if we assume that in some cases the infection may occur in the houses of the people, it is not unreasonable to assume that the excremental matter which gets into the milk at its source is the cause of the majority of cases.

The remarkable decrease of mortality amongst the infants at the New York Foundling Asylum after the introduction of clean milk and of a milk sterilisation plant is a further proof of the deleterious nature of the bacteria found in milk, and the results obtained in many other institutions and towns with municipal milk supplies corroborate it.

To quote Sir J. Crighton Browne, "measures must be taken to secure a supply for our infants, our children, our invalids, for all classes, of uncontaminated milk of proper nutritive standard. We must have pure milk."

Infantile tuberculosis and infantile diarrhœa show little, if any, signs of diminishing. All our sanitary improvements have had little or no effect because they have not reached the cause of the evil, the impure milk supply.

By improving our water supplies we have reduced the mortality from typhoid fever to an enormous extent; by improving the houses of the working classes and improving the conditions of labour, typhus fever has become almost unknown, consumption of the lungs has decreased continuously, and many other diseases have become far less prevalent and fatal.

Tuberculosis in children and infantile diarrhœa are just as preventible diseases as any of those mentioned, if we set about preventing them in the way indicated by modern science.

The evidence which I have deduced shows that there can no longer be any doubt that impure milk is one of the chief causes of the excessive and continued mortality from these diseases. Hence the great importance of insuring a pure milk supply. Incidentally it may be mentioned that, besides diminishing infantile mortality, a pure milk supply would be a great aid to temperance. Only those who have quaffed pure cold milk in summer know how delicious it is. Those whose only acquaintance with milk as a beverage is derived from drinking it as supplied at refreshment-rooms and bun shops have no idea of what milk should be. I very rarely taste milk, yet I know no beverage in summer to equal cold pure milk, and if I could be sure of obtaining it, I should greatly prefer it to the beverages I am compelled to select. The amount of milk consumed at the present time is only a portion of what it would be if public confidence were gained, and this greatly increased demand would benefit the very persons whom we are urging to supply us with what we want.

First and foremost, we demand that it should be a criminal offence for anyone to sell milk taken from a cow obviously suffering from disease unless a veterinary surgeon has certified that such disease will not affect the milk. No one would knowingly drink milk from a diseased cow, and the public should be protected from having to do so unknowingly. This, no doubt, would imply frequent veterinary inspection, but veterinary inspections now take place when anthrax and certain other diseases are suspected, and this merely to prevent disease spreading amongst cattle. Surely one human being is worth a good many cattle, and the prevention of the spread of disease from cattle to man is infinitely more important than the spread of disease amongst a herd of cows or a lot of swine.

But this question of veterinary inspection I need not labour, as I feel that I have said enough to convince the most sceptical that proper veterinary inspection of the milk cows is imperative.

Our next demand is the more thorough inspection of the cowsheds and dairies and increased supervision over the conditions under which the milk is produced.

Every sanitary authority has power to make regulations for enforcing the provision of sufficient air space for the cows, for securing proper drainage and water supply, and for securing cleanliness generally. Unfortunately, many authorities have not adopted such regulations; but, still more unfortunately, the majority of those who have either do not properly enforce them or say that they are powerless to enforce them.

From a wide experience I have no hesitation in saying that at the present time the majority of the places at which milk is produced are unsatisfactory. In very many there is no proper water supply, more or less polluted water being used for dairy purposes. Enormous accumulations of manure lie in the immediate vicinity of the cowsheds, often in the cow-yard into which the cows are turned in the winter for an airing.

The cowsheds are filthy, the walls and floors being plastered with manure. The ventilation and lighting are defective. Proper lighting is especially neglected.

The excuse given by dairymen for the existence of bad dairy conditions is that he cannot afford the time necessary to produce clean milk and that he cannot get his men to carry out his instructions. One man informed me that if he were to insist upon his men carrying out all the reforms I required, especially those referring to the cleansing of the cows and to the personal cleanliness of the men themselves, that they would leave in a body.

I do not believe this, for I have experience to the contrary. I know many dairy farms where all the cows are groomed daily, where washing utensils are provided in every cowshed, and overalls and caps are worn by every milkman. The managers see that everything is kept clean. One farmer informed me that he had at first some trouble in getting the men to carry out his instructions, but when they saw that he was in earnest and meant to have them carried out they were and are carried out, and he has not had to engage a single additional hand. It costs him no more to produce his milk under cleanly circumstances than it did previously under the unclean conditions. It is useless a master giving instructions or hanging up printed instructions in his cowsheds if he does not himself rise early and see that they are obeyed. One sanitary authority issued large cards of printed instructions to milkers and had them distributed. I found some of these prominently displayed in cowsheds where every instruction was ignored and where the cows were in a disgustingly filthy condition. There they are, said the cowkeeper, I cannot make the men carry them out.

It is perfectly certain that until the public bodies now entrusted with authority have additional powers and are compelled to assert their authority, or until the powers now, or to be, conferred upon them are delegated to some other bodies which will either themselves enforce them, or see that the sanitary authorities enforce them, very little progress will be made. Meanwhile we must continue to use dirty milk or be driven to use such substitutes as tinned milk or dried milk, or sterilised, or pasteurised milk, or we must go without milk.

It may be difficult and an expensive matter in some cases to obtain a good and copious water supply, but a farm should not be used as a dairy farm unless it has such a supply.

If clean milk is to be supplied it must be clean from the beginning; I have no faith in filters and strainers. This is a case in which "Prevention is better than cure." Keep out the polluting matter, it is easier and cheaper and infinitely preferable to keep out the filth than to remove it afterwards by any process whatever.

(To be continued.)

IONIC MEDICATION
IN THE TREATMENT OF SOME OBSTINATE CASES OF
PELVIC DISEASE IN WOMEN. (a)

By SAMUEL SLOAN, M.D., C.M. GLASG., F.F.P.S.,

Consulting Physician to the Glasgow Maternity Hospital, and to the Glasgow Hospital for Diseases of Women.

THE author explained that ionic medication was the application of electro-chemistry to therapeutics. He showed diagrammatically the probable position and behaviour of the ions—molecules and atoms—in the case of water: first, when not influenced by any electro-motive force; secondly, when an E.M.F. of 1 volt is applied; and thirdly, under at least 2 volts, when decomposition of the water takes place. He next demonstrated the existence of free ions in a solution of common salt, by showing that a current could be set up by the mere insertion of two carbon electrodes into the solution, giving evidence at the same time that these electrodes did not differ in potential. He explained that, whereas in the case of simple electrolysis the changes took place at the poles only, in the case of ionic medication, on the other hand, the changes took place from the active pole into the tissues in the direction of the neutral pole; iodine, etc., from the negative pole; copper, etc., from the positive pole; these being the two substances which he had used in this treatment.

He quoted from Prof. Howard A. Kelly's new book on "Medical Gynæcology," to prove how obstinate were most of the cases of sepsis of the genital tract in women, and then proceeded to refer to some cases of obstinate septic disease accompanied with purulent discharge, which he had treated by ionic medication. The success had, in his hands, been most gratifying, a cure having practically resulted in nearly all his cases, after a short term of treatment. The same may be said of his treatment of cases of hæmorrhage.

The solution he employed was, in the case of copper, 1 per cent. of the cupric chloride. The vulva is first treated by being carefully packed with cotton-wool soaked in the solution; then the medication is applied to the vagina in a specially-made glass speculum containing a spiral of copper wire, and filled with the copper solution. When vulva and vagina have been rendered aseptic, a specially-constructed cervical electrode is passed through the speculum as far as the inner os. A few applications, say, three or four, at intervals of three or four days, usually suffice to render this cavity normal. The endometrium is next treated by means of a long, curved and grooved copper electrode passed up to the fundus. The patient during the applications is placed on her back with a bed-slipper under the pelvis. When the affection partakes of a sub-acute nature he prefers to use iodine as the ionic agent, the solution employed being a 2 per cent. one of iodide of potassium combined with 0.2 per cent. solution of liquor iodi.

His electrode holder is kept in position by a bag of shot which rests on the broad end of the holder on the couch, this holder serving to keep the speculum in position. The current he employs is from a battery of Leclanché cells of good size, and about twenty in number, the amount of current varying from 10 to 20 m.a. for 15 to 20 minutes.

(a) Abstract of paper read at the meeting in Glasgow of the Electro-Therapeutic Section of the Royal Society of Medicine, May 22nd, 1908.

The neutral electrode, he advises, is one made of copper gauze covered with wet sculptor's clay, on which the patient's hands rest.

Since he began this form of treatment he has seldom required to employ curettage in the treatment of septic endometritis, and he believes that no other form of treatment will give results in any way approaching those to be obtained from ionic medication.

THE CURE CRAZE OF TO-DAY. (a)

By R. MURRAY LESLIE, M.D., M.R.C.P. Lond.,

Physician to the Prince of Wales Hospital, Physician to the Royal Hospital for Diseases of the Chest, &c.

"Cures" of all kinds, it is hardly needful to point out, are as ancient as history itself. Homer refers to the cure of Hercules by Minerva at the springs of Thermopylæ—cures by hot air baths and hot springs were well known to the ancient Greeks—and Hippocrates himself recommended them to his patients. Hydropathic cures were largely practised by the Romans. Julius Cæsar had his health restored by the sulphur springs of Cauterets; Nero regularly visited the vapour baths of Pozzioli; while the wonderful remains of the Roman thermæ at Pompeii, Pragnieres, Bath, and countless other places, show how universal was the custom amongst the Romans of taking the cure.

It would be impossible to refer to all the cures in vogue at the present day. There is the rest cure, the open-air cure, the hydropathic cure, the various bath and thermal cures, the mud cure, the massage cure, the sun cure, the light cure, the Weir-Mitchell cure, the Salisbury cure, the Chittenden cure, not to speak of the multitude of cures associated with individual health resorts, such as the Plombieres cure, the Nauheim cure, the Aix cure, the Vichy cure, the Marienbad cure. There are cures for making people fat, and still more numerous ones for making them thin, while in addition to these more or less legitimate cures there are hundreds of quack cures, whose devotees or victims may be numbered by thousands, and there are religious and ostensibly religious cures, such as the Lourdes cure and the Christian Science cure.

The existence of all these cures is no doubt partly a question of demand and supply, and partly one of obedience to the dictates of fashion. The demand is the outcome of the strain, stress, and hustle of modern life. Competition is so keen that the business man drains his mental and physical energy. He is constantly on the rack, with insufficient leisure to recruit his energies, and even his spare time is fully occupied with his social or other duties, or it may be with his pleasures and dissipations. He eats too much, sometimes drinks too much, and sleeps too little. The professional man works, if possible, still harder. The growing army of women engaged in business and professional pursuits often work far beyond their strength, regardless of ill-health and of natural and acquired ailments. The fashionable woman has to work still harder. She has her ceaseless round of social duties and pleasures—her shopping, her dressing, her lunch parties, her bazaars, her afternoon calls and "at homes," her dinners, bridge parties and dances, and then snatches a few hours' sleep before re-commencing her next day's round. In her sane intervals she has to acquire a smattering of the current political and other topics of the day for conversational purposes. In fact, on all hands the candle is being burnt at both ends, and the bodily system is taxed and racked beyond its limits of endurance. The result is nervous breakdown, brain fag, physical exhaustion, and disordered functions of the bodily organs, with their thousand-and-one manifestations.

Desperate illnesses require desperate remedies, hence the necessity of cures planned to suit the different needs of the individual. There is, however, another factor at work which must not be ignored. There has arisen an almost morbid interest in all questions relating to personal ailments. Appendicitis is quite as common a topic of conversation as the merits or demerits of the Directoire costume, and such matters are probably the commonest subjects of conversation at the present day. What a boon it would be if there were similar eagerness to discuss the necessity and practice the art of living a natural hygienic life which would avoid the many evils that the different cures are designed to treat, and it is one of the main objects of this Institute to inculcate these elementary principles of hygiene among the younger women of England and the future mothers of our race.

The factors more or less common to all cures are rest, fresh air, sunlight, change, regulation of diet, daily exercise, and faith, most of which are comparatively easy of attainment by the well-to-do.

(a) Summary of Address delivered at the Institute of Hygiene, May 26th, 1908.

CLINICAL RECORDS.

CASE OF ANEURYSM OF THE DESCENDING AORTA.

By R. O. MOON, M.D.

H. C., a carman, æt. 37, came up to my out-patient department at the Heart Hospital, in January, 1908, complaining of pain in the left lumbar region for the last 18 months, which was gradually becoming worse.

Family History.—Father died of rheumatism, and mother of apoplexy.

Previous History.—At the age of 18 he had syphilis, for which, apparently, he did not undergo any lengthy course of treatment. Since then he had enjoyed good health till 1½ years ago, when he describes himself as having been caught somewhat suddenly by pain in the left side. For about a fortnight he was quite unable to move. After that he was able to get about, but was obliged to give up his work entirely, and was never entirely free from pain. For the past six months he had had dyspnœa and palpitation of the heart on exertion.

The examination of the heart showed the apex beat to be within the nipple line, the impulse heaving, and a soft systolic murmur traceable into the axilla. Examination of the lungs, however, presented complete dulness over the left lung posteriorly from the base to the spine of the scapula and in the axilla; the TVF was much diminished; on the other hand, the air entered well.

The pain was very definitely localised to the left lumbar region, which was tender on pressure. At times the pain, which was of a continuous gnawing character, extended to the epigastrium, but there was no pain on percussion of the vertebræ. A diagnosis was made of aneurysm of the descending aorta. The possibility of a mediastinal growth was ruled out partly on account of the age of the patient, and also because a growth would almost certainly have proved fatal in 18 months. Then, too, there was the history of syphilis, which, of course, pointed to aneurysm. The X-rays showed a large tumour in the left chest, but were not helpful as to its nature.

While in hospital he did not get much relief from iodide of potassium, but fortunately the pain was by no means so severe as is often the case with aneurysm, and only once did he require morphia. He went out of the hospital at his own request after six weeks, and a week later suddenly became faint, fell to the ground, and died a few minutes after the arrival of the doctor who had been summoned. As the latter knew nothing of the case, an inquest was held, and I heard later that a large sacculated aneurysm of the descending aorta, some 5 inches from the diaphragm was found, which had thus suddenly ruptured.

The case seems to be of some interest from the suddenness of the initial onset of the pain, and from the fact that the pain, though continuous, was never very severe, and remained the only symptom of the disease till the final rupture of the aneurysm.

OPERATING THEATRES.

GUY'S HOSPITAL.

Laparotomy for Cancerous Growth. — Mr. Arbuthnot Lane operated on a woman, æt. 34, who was suffering from a cancerous growth of the rectum involving the posterior surface of the uterus. He opened the abdomen by a vertical incision ¾ inch to the left of the middle line and extending from the umbilicus to the symphysis pubes. The sigmoid was separated from the iliac fossa to which it was fixed as is usual when distal obstruction exists by firm adhesions. In the same way the left ovary and tube had become involved in the peritoneal bands. The growth in the rectum was then defined, when it was found that the infection of the uterus was limited to the junction of the body and cervix. The uterus was removed together with the entire rectum and meso-rectum, with a portion of the meso-sigmoid, the bowel being brought out through the abdominal incision. Then it was divided, and sufficient length only being left to connect up with the special arrangement of tube and bag which Mr. Lane employs in these cases, and which is so efficient for the purpose of cleanly drainage. He then closed off the true pelvis by suturing the peritoneum covering the bladder and broad ligaments to the peritoneum covering the posterior margin of the pelvic inlet. A piece of gauze was then placed in the pelvis below this artificial peritoneal diaphragm, which separated the true pelvis from the remainder of the peritoneal cavity. During the greater part of the operation a quantity of saline solution was passing into the subcutaneous tissue of the axillæ. This was continued for several days. The patient was doing exceedingly well five days after the operation.

On the same day Mr. Arbuthnot Lane operated on a man who had a cancerous mass in the sigmoid which produced marked obstruction. The abdomen was opened in a manner similar to the last. The growth was found to involve the sigmoid for an area of three inches. It had dropped into the case of the pelvis, where it lay to the left of the middle line fixed to the bladder, which was involved in the growth over an area of one and a half inches square. The growth, with the peritoneal and muscular coat of the bladder to which it was attached, was removed from the pelvis, and brought out through the abdominal incision. It was then freely excised with the area of meso-sigmoid corresponding to it. Continuity of the sigmoid was then effected by an end-to-end junction. The damage sustained by the bladder was met by the accurate approximation of the incised peritoneal margins. The progress of the case was excellent.

Operation for Fractured Femur in a Child.—Mr. Arbuthnot Lane also operated on a young child who had been struck by a motor-car, and who had sustained a somewhat irregular transverse fracture of the femur at the level of the trochanter; the upper extremity of the shaft was displaced upwards and inwards upon the upper fragment, and this displacement was only exaggerated by traction and manipulation. The seat of fracture was exposed by a vertical external incision when an attempt was made to replace the fragments in apposition by traction on the limb. It was then seen that the traction on the shaft caused the upper fragment to rotate around an axis running antero-posteriorly through the head of the femur, and so render replacement impossible. It was attempted to control this rotation of the upper fragment first by traction in an upward direction in the trochanter, but this resulted only in damage to this structure, which was very fragile. A similar result followed an attempt at reduction by the introduction of an elevator between the fragments, the exercise of any leverage being followed by some scrunching of the broken surfaces. Finally, by adducting the thigh very forcibly the upper end of the shaft was protruded outwards through the incision, and accurate apposition was at last obtained. The replacement was very difficult and prolonged. Mr. Arbuthnot Lane pointed out that in his experience this fracture occurring in young life was the most difficult he knew to deal with, and after it he would put a similar fracture of the humerus at the same period of life. The difficulties in the way of replacement were the mobility and fragility of the upper fragments. When the fragments of the femur were accurately apposed they were retained in position by a dumb-bell shaped steel plate with three screws, two of which received the shaft, one the upper fragments. The screws employed were those he had chosen for fractures of the patella, and such fractures in which only a proximal compact tissue could be easily dealt with. They were half-inch screws threaded up to the head, the smooth barrel being absent. This form of screws in the peculiar circumstances offers special advantages. The absence of the barrel is not material to the functioning of the screw, since friction and not approximation are required of it. The child is making the uninterrupted recovery which is universal in this class of case.

SPECIAL REPORTS.

GENERAL MEDICAL COUNCIL.

EIGHTY-SEVENTH SESSION.

FIRST DAY.—Tuesday, May 26th, 1908.

The President, Dr. MacAlister, in the Chair.

The President read his address. He began by referring in a few well-chosen words to the regretted deaths since the last session of Sir Thomas McCall Anderson, of Sir Patrick Heron Watson, and of Dr. James Bell Pettigrew. He then stated that the University of Glasgow had done him the honour of appointing him, as from May 27th, to be its representative on the Council. He therefore proposed to resign on the morrow the seat to which he was elected some nineteen years ago by his fellow-graduates of the University of Cambridge. This would necessitate his vacating the Presidential chair. He pointed out that in the direction of finance the Council could look back with satisfaction, the surplus in 1907 being £1,095, even after £415 had been paid towards the expense of enlarging the Council chamber and of improvements, one of the most important being the erection of a light gallery specially reserved for representatives of the Press. The President next referred to the recognition of the degree of Doctor of Medicine of the McGill University of Montreal and the Laval University of Quebec; also to the question of restraining medical practice by unqualified persons. After mentioning the medical faculty of the University of Wales, and speaking of the work performed by the various committees of the General Medical Council, Dr. MacAlister finished his address with the following words:—"In conclusion, I would remind the Council that its first meeting was held on November 23rd, 1858, pursuant to a summons by the Secretary of State at the Royal College of Physicians of London, and under the Presidency of Sir Benjamin Brodie. Our next session in the ordinary course will begin on November 24th, 1908, and the Council will just have completed the first fifty years of its existence. . . . I suggest that we should celebrate our jubilee by a friendly reunion, to which all who survive of the past members of the Council should be invited. . . ."

Moved by Dr. LITTLE, seconded by Dr. NORMAN MOORE, and carried by acclamation:—"That the President be thanked for his address, and requested to let it be printed in the minutes."

On motion from the CHAIR, it was agreed:—"That the following constitute the Business Committee:—Dr. Norman Moore, Chairman; Mr. Young, The President, Sir Christopher Nixon.

Moved by Dr. NORMAN MOORE, seconded by Mr. THOMSON, and agreed to:—"That the Council do adjourn after 4 p.m. to enable certain committees to meet for the completion of their reports."

Moved by Dr. NORMAN MOORE, seconded by Sir JOHN MOORE, and agreed to:—"That the following yearly tables be received and entered in the minutes":—

(*a*) I. and II. Tables showing Results of Professional Medical Examinations during 1907.

(*b*) Table showing Results of Professional Examinations for Qualifications in Sanitary Science, Public Health, or State Medicine during 1907.

(*c*) Table showing Results of Professional Dental Examinations during 1907.

(*d*) Table showing Results of Preliminary Examinations during 1907.

(*e*) Answers sent by the Medical Authorities as to the exemptions granted by them in any part of their Examinations during the year 1907

(*f*) Table showing Results of Competition held on May 4th, 1908, for Commissions in the Medical Staff of the Royal Navy.

(*g*) Table showing Results of Competition held in January, 1908, for Commissions in the Indian Medical Service.

Moved by Dr. MCVAIL, seconded by Sir CHRISTOPHER NIXON, and agreed to:—"That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, and the Under-Secretary of State for India respectively, for the returns which they have again furnished to the Council, with the request that these returns may in the future continue to be furnished to the General Medical Council."

Moved by Dr. SAUNDBY, seconded by Sir CHRISTOPHER NIXON, and agreed to:—"That in future such regulations of the General Medical Council as have been passed from time to time relating to the conduct of members of the medical profession shall be included in the matter published in the *Medical Register*."

Moved by Dr. SAUNDBY, seconded by Sir CHRISTOPHER NIXON, and agreed to:—"That in future such regulations of the General Medical Council as have been passed from time to time relating to the conduct of members of the dental profession shall be included in the matter published in the *Dentist's Register*."

Moved by Sir HUGH BEEVOR, seconded by Mr. MORRIS, and agreed to:—"That Mr. Peyton Todd Bowman Beale, F.R.C.S.Eng., L.S.A., be appointed Assistant Examiner in Surgery to the Apothecaries' Society of London vice Mr. Stonham, who retires by rotation."

Dr. ADYE-CURRAN asked whether the Assistant Examiners in Surgery to the Apothecaries' Society of London would be directed to report on the other two subjects of the Final Examination.

The PRESIDENT answered that the Council might so direct it if it saw fit.

Read:—A report by the Executive Committee pursuant to the following standing order:—"The Executive Committee shall be empowered to take the necessary steps for carrying into effect the clauses of the Medical Act (1886) relating to the registration of the diplomas of colonial and foreign practitioners, and shall report to the Council, from time to time, their proceedings thereon.—(1887, XXIV., 270)."

REPORT.

The Executive Committee report that Part II. of the Medical Act (1886) having been extended by an Order in Council to the Province of Quebec, they have considered the conditions under which certain medical qualifications granted in the Province shall be recognised for registration in the Colonial List of the *Medical Register* of the United Kingdom, and on May 25th, 1908, adopted the following resolution:—

"That any person who holds—(1) The Degrees of Doctor of Medicine and Master of Surgery of McGill University, Montreal, together with the Licence to practise in the Province of Quebec; or (2) The Degree of Doctor of Medicine of Laval University, Quebec, together with the aforesaid Licence to practise, shall be entitled to be registered in the Colonial List of the *Medical Register*, provided he satisfies the Registrar of the General Medical Council regarding the other particulars set forth in Part II. of the Medical Act, 1886."

On motion from the CHAIR it was agreed unanimously:—"That this report of the Executive Committee be received and entered on the minutes; that the Registrar be directed to give effect to the resolution therein contained, and that the Council record its satisfaction at the establishment of reciprocal relations with the Province of Quebec, and its desire that similar relations may soon be established with the other Provinces of the Dominion of Canada."

On motion from the CHAIR, and agreed to:—"That the report of the Executive Committee on the question of the duties of Assistant Examiners of the Apothecaries Hall, Dublin, be received and entered on the minutes." The report contained recommendations that the Assistant Examiners be instructed to conduct the surgical portion of these examinations, and, in addition, to supervise the medical and obstetrical portions. . . . Also that the Examiners be instructed to report fully for the information of the Council as to the methods and standards actually adopted at each qualifying examination, and as to the steps they have taken in fulfilment of the duties imposed upon them by Section 5 of the Medical Act, 1886."

It was subsequently agreed to, on the motion of Mr. MORRIS, seconded by Dr. LINDSAY STEVEN:—"That the further consideration of the report be adjourned to a later period of the session in order that Mr. Lushington may be present."

Strangers having withdrawn, the Council deliberated *in camerâ*, and, on their re-admission, the PRESIDENT announced that the name of Dr. John Shaw had, at his own request, been removed from the *Medical Register*.

The Council then adjourned.

SECOND DAY.—WEDNESDAY, MAY 27TH, 1908.

The President, Dr. MACALISTER, in the Chair.

The official notification of the appointment of Dr. Donald MacAlister as representative of the University of Glasgow for five years from May 27th, 1908, having been read, Dr. MacAlister vacated the chair, which was taken by Mr. Tomes as Senior Treasurer. Dr. MacAlister having been introduced to the Council as representative of the University of Glasgow by Sir John Batty Tuke, it was proposed by Dr. LITTLE, seconded by Dr. MCVAIL, and agreed to unanimously, "That Dr. Donald MacAlister be elected President of the General Medical Council." He thereupon took the chair.

After it had been agreed to unanimously that the President, Treasurers, and Chairman of the Business Committee be appointed a Committee to make arrangements for the celebration of the Council's Jubilee in November, 1908, the Council resumed the consideration, adjourned from November 27th, 1907, of the case of Duncan Shaw Morrison, M.B., M.S.Edin., who had been summoned before the Council on account of having been convicted on three different occasions at the Lochgilphead Police Court for breaches of the peace and contravention of the Licensing Act, Scotland.

Mr. Morrison was called, but did not answer to his notice. On the re-admission of strangers after the Council had deliberated *in camerâ*, the President announced that the Registrar had been directed to erase from the *Medical Register* the name of Mr. Duncan Shaw Morrison.

The Council proceeded to the consideration, adjourned from November 29th, 1907, of the case of William Henry Roberts, L.R.C.P. and S.Edin., who had been summoned before the Council on the charge of having assisted unregistered dentists.

Mr. Roberts attended, and the British Dental Association was represented by Mr. Hart. On the re-admission of strangers after the Council had deliberated *in camerâ*, the President announced that the Council, having further considered the facts, does not judge Mr. Roberts guilty of infamous conduct in a professional respect.

In the adjourned case from November 29th, 1907, of Morgan Watkin Williams, M.B., B.S.Glasg., who had been summoned before the Council on the charge of enabling an unqualified and unregistered person, Mr. Frank Hannah, to engage in medical practice, the President, on re-admission of strangers, announced a similar result.

The consideration of the case of Christopher Richard Kempster, M.R.C.S.Eng., L.R.C.P.Lond., of Melbourne, charged with advertising himself and associating himself with the Freeman and Wallace Electro-Medical Institute of Melbourne and Sydney, was adjourned to the November session.

The Council next considered the case of James Brookes, Birmingham, L.R.C.P.Edin., L.F.P.S.Glasg., who had been summoned before the Council on the charge of having allowed an unqualified and unregistered person, J. W. Austin Brookes, to attend patients, prescribe for them, and sign certificates on his (James Brookes') behalf. The matter was brought before the Council by the Education Committee of the City of Birmingham.

Mr. Brookes was accompanied by his solicitor, Mr. John Pritchard, of Birmingham. The solicitor of the Council, after witnesses in the case had withdrawn, read the notice and several statutory declarations, amongst others those of Mr. Stevenson, Chief Superintendent of the School Attendance Officers, and Mr. Peter Banks, Chief School Attendance Officer, who were both called as witnesses, being examined and cross-examined, and answering questions from the Chair, the legal assessor and members of the Council. Several other witnesses were examined; amongst them was a child of 10 and a girl of 14, also a blind man. After addressing the Council, Mr. Pritchard called Mr. James Brookes, and also Mr. J. W. Austin Brookes. Both were examined and cross-examined.

It was then moved by Sir Christopher Nixon, seconded by Dr. McVail, and agreed to:—"That the Council do adjourn its decision in the case until the following day"

The Council then adjourned.

THIRD DAY.—Thursday, May 28th, 1908.

The President, Dr. MacAlister, in the Chair.

The Council resumed the consideration, adjourned from Wednesday, May 27th, of the case of James Brookes.

When strangers were re-admitted after the Council had deliberated *in camerâ*, the President, addressing Mr. Brookes, said:—"Mr. James Brookes, I have to announce to you that the Council, having carefully considered the facts proved against you, have directed the Registrar to erase your name from the *Medical Register*."

The Council proceeded to the consideration, adjourned from November 27th, 1907, of the case of John P. Rafter, L.A.H. Dublin, L.K.Q.C.P. Ireland, L.Midw.R.C.S. Ireland, registered as of 338, Stanley Road, Bootle, Liverpool, who had been summoned on the charge of having systematically sought to attract patients in Great Crosby and Waterloo, Lancashire, by the distribution of cards from house to house and in the street.

The complainants were the Medical Defence Union, which was represented by Dr. Bateman. Mr. Rafter attended in answer to his notice, and put in several certificates as to character, both from medical men and civic functionaries. He addressed the Council on his own behalf.

When strangers were re-admitted after the Council had deliberated *in camerâ*, the President, addressing Mr. Rafter, said:—"Mr. Rafter, I have to inform you that the Council, having further considered the facts proved against you, do not judge you guilty of infamous conduct in a professional aspect."

The Council considered the case of Frederick Aubin Monks, registered as of Woodcliffe House, Burgess Hill, Hampstead, N.W., L.S.A. Lond., 1871; M.R.C.S. Eng., 1871; L.R.C.P. Edin., 1873, who had been summoned to appear before the Council on the following charge:—"That you abused your position as a medical man by having sexual intercourse with a patient, namely, Annie Rose Le Farre (or Ely), whom you were attending professionally at your surgery, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Medical Defence Union.

Mr. Monks attended in answer to his notice with Mr. C. F. Gill, K.C., his counsel, instructed by Mr. Freake Palmer, his solicitor.

Dr. Bateman appeared on behalf of the Medical Defence Union.

The Solicitor having read the notice to attend, Dr. Bateman read the declaration which had been made by himself and an extract from the depositions taken at the Police Court when a charge was preferred against Mr. Monks.

Mr. C. F. Gill, K.C., then addressed the Council on behalf of Mr. Monks. This discourse tended to show that Rose Ely had not been Mr. Monk's patient at the time of the intercourse, and also opened up her past life. He read a letter which had been written by Mrs. Annie Rose Ely, in answer to an advertisement in *The People* newspaper, and tendered Mr. Monks as a witness.

The Solicitor read a letter of explanation which Mr. Monks had written to the Registrar.

Mr. Monks was cross-examined as to some letters written by him to Mrs. Ely. Mr. Monks was re-examined by Mr. Gill, and answered questions put to him by the Legal Assessor, and by members of the Council through the chair.

This closed the case for Mr. Monks.

Mr. Monks and strangers having been re-admitted after the Council had deliberated *in camerâ*, the President announced the judgment of the Council as follows:—"Mr. Monks, I have to tell you that the Council have come to the conclusion that the facts alleged against you in the notice of inquiry have not been proved to the satisfaction of the Council."

The Council considered the case of Stanley Southam, registered as of 512, Rochdale Road, Manchester, L.S.A. Lond., 1900, who had been summoned to appear before the Council on the following charge:—"That you acted as 'cover' to an unregistered dentist, namely, Mr. Sydney Smith, of 163, Conran Street, Harpurhey, Manchester, by systematically acting for him in your own surgery in respect of the treatment of patients sent to you by him for dental operations requiring an anæsthetic, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Medical Defence Union.

Mr. Southam attended in answer to his notice, accompanied by Mr. William Vickers Hamilton, his solicitor.

Dr. Bateman attended on behalf of the Medical Defence Union.

The Solicitor having read the notice, Dr. Bateman opened the case for the complainants. He read declarations which had been made by Mrs. Emma Marshall, Miss Clara Furlong, Mr. Roland Salt, Miss Nellie Haxby, and Miss Florence Ada Quinn.

Mr. Hamilton then opened the case for Mr. Southam. He read a declaration which had been made by Mr. Southam on April 7th, 1908. He tendered Mr. Southam, and examined him as to the accuracy of a further declaration which he had made, and which he put in. Mr. Southam was cross-examined, and answered questions put to him by the Legal Assessor and by members of the Council.

Strangers having been re-admitted after the Council had deliberated *in camerâ*, the **PRESIDENT**, addressing Mr. Southam, said :—" Mr. Southam, I have to inform you that the Council having considered the facts alleged against you have come to the conclusion that the facts have not been proved to their satisfaction."

The Council considered the report of the Dental Committee on the charge against Arthur Ward (in practice before July 22nd, 1878), the British Dental Association being the complainants. The Committee had found the following facts to be established by the evidence :—" He has issued and circulated a pamphlet containing statements of an objectionable character, viz., laudatory statements as to his own skill and methods, and depreciatory statements as to the work of other practitioners and claims of superiority over other practitioners. After receiving notice of the charge in this case he withdrew the pamphlet and issued another which omits certain depreciatory statements as to the work of other practitioners, but contains certain laudatory statements as to his own skill and methods. He expressed his willingness to undertake to withdraw the pamphlet altogether, and not to issue any similar advertisements in future."

Mr. Ward attended, accompanied by Mr. Coley, his solicitor.

Mr. **HART**, representing the British Dental Association, addressed the Council, and Mr. **COLEY** replied.

After the Council had deliberated *in camerâ*, the **PRESIDENT**, on strangers being re-admitted, said that the Council had adjourned the further consideration of the case till November.

The Council considered the report of the Dental Committee on the charge against William John Watson.

The Committee find that the following facts were established by the evidence :—

William John Watson was registered in the *Dentists' Register* on December 31st, 1878, as in practice before July 22nd, 1878, and his address in the *Register* for the current year is 8, New Street, Birmingham. In the year 1881 the qualification of Licentiate in Dental Surgery of the Royal College of Surgeons, Edinburgh, was added to his name in the *Dentists' Register*. He was, however, deprived of that diploma by the College in the year 1891 for advertising contrary to the declaration signed by him on admission. In the year 1901 the said William John Watson caused to be printed, issued, and circulated a pamphlet containing statements of an objectionable character—viz., laudatory statements as to his own skill and methods, and depreciatory statements as to the work of other practitioners and claims of superiority over other practitioners. This pamphlet contains a statement that the said William Watson had obtained the above-mentioned diploma by examination. Testimonials are also printed in the pamphlet which state that the said William John Watson possesses the said diploma. These testimonials are not dated, but they were, in fact, given before 1891 (when the said William John Watson was deprived of the said diploma) to assist him in obtaining an appointment he was then proposing to apply for. In the year 1903 or in the year 1906 (the evidence was not clear as to which date) the said William John Watson instructed his printer to destroy the remaining stock of these pamphlets, and the bulk of them were then destroyed, but one parcel was not destroyed, and some of these were recently distributed. The said William John Watson stated that these copies were accidentally discovered, and that they were distributed inadvertently, and that the remainder have since been destroyed. He undertook in future not to issue the same or any other similar pamphlet, and to discontinue all advertisements.

Mr. Watson attended, accompanied by Mr. A. C. Hayes, his solicitor, who addressed the Council on behalf of his client.

After the Council had deliberated *in camerâ*, the **PRESIDENT**, on strangers being re-admitted, said that the Council had deferred the further consideration of the report till November, when Mr. Watson would require to be present and present satisfactory evidence as to his conduct in the interval.

The Council then adjourned.

FOURTH DAY.—FRIDAY, MAY 29TH, 1908.

The President, Dr. **MACALISTER**, in the Chair.

The Council first received a communication *in camerâ*.

The whole time of the meeting was then occupied by the consideration, adjourned from November 29th, 1907, of the case of John Papa Nicolas, registered as of 87, Dowanhill Road, Catford, S.E., M.R.C.S.Eng., L.R.C.P.Lond., who had been summoned on the following charge :—"That you have systematically canvassed in Catford for patients by personal visits to patients of Mr. Thomas William Atkinson and others, both while you were in the employment of the said T. W. Atkinson and subsequently, and that in the course of such canvass you disparaged the qualifications and skill of the said T. W. Atkinson, and extolled your own, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the London and Counties Medical Protection Society.

Mr. J. P. Nicolas attended in answer to his notice, accompanied by Mr. H. L. Randolph Hemming, his solicitor.

The London and Counties Medical Protection Society were represented by Mr. Alec Neilsen, counsel, and Dr. Hugh Woods, Secretary to the Society.

Mr. **HEMMING** read a statement which he had prepared taking exception to the right of the Council to proceed with this case, and urging that the Council had no jurisdiction under Section 29 of the Medical Act, 1858, to try Mr. P. Nicolas on a charge of infamous conduct in a professional respect.

The **LEGAL ASSESSOR** directed him to hand in his objection, which, he stated, could not be entertained.

Mr. **HEMMING** took a further objection to the Council dealing with the case on the grounds of prejudicial and oppressive irregularities, and the alleged breach of Standing Order, Chapter XIV., 3 (c).—The **LEGAL ASSESSOR** advised the Council that the objection was not well founded. Mr. Hemming was requested to hand it in.—Mr. **HEMMING** took a further objection to the President presiding at the hearing, on the ground that he had already presided over the meeting of the Penal Cases Committee, and had formed a judgment in regard to the case. Also that Mr. Papa Nicolas had not had an opportunity of being heard by the Penal Cases Committee.—Mr. Hemming was requested to hand in his objection. The **LEGAL ASSESSOR** advised the President and the Council that this also was not well founded.—Mr. **HEMMING** then lodged a further objection to any member of the Penal Cases Committee taking any part in the proceedings. The **LEGAL ASSESSOR** advised the Council that this also was not well founded.

Mr. **NEILSEN** then called Mrs. Agnes Mary Murphy as a witness, whereupon Mr. Hemming took a further objection that the Standing Orders had not been complied with, inasmuch as the complainant had supplied no statutory declaration as to the facts within the meaning of the rules. This objection was also handed in. The **LEGAL ASSESSOR** advised that it was not well founded.—Mr. **HEMMING** took objection that Standing Order, Chapter XIV., 16, had not been complied with. The **LEGAL ASSESSOR** explained that this rule had no reference to cases adjourned from day to day, but to those in which the facts had been found to be proved, but judgment had been postponed. Mr. **HEMMING** attempted to raise another objection which the **LEGAL ASSESSOR** ruled had reference to the merits, and could be dealt with later.

Mr. **HEMMING** then requested that Mr. Atkinson should be recalled for further cross-examination. The **LEGAL ASSESSOR** advised that this should not be permitted, as Mr. Atkinson had already been examined, and cross-examined, and re-examined by Dr. Hugh Woods.

Mr. Hemming then took an objection on the ground that the Standing Orders, Chapter XIV., 12, had not been complied with. This objection was over-ruled.—Mr. Hemming took further objection to the manner of the printing and circulating of the documents and evidence, and also to the fact that, as he alleged, his client had no proper opportunity of preparing his defence in November, 1907.—Mr. Hemming took further objection to the form of the charge, and to the words "and to others" which he desired to have struck out.—The Legal Assessor ruled that, as no evidence would be tendered, Mr. Papa Nicolas was entitled to an acquittal so far as the charge that he had systematically canvassed in Catford for patients by personal visits to persons other than patients of Mr. Thomas William Atkinson was concerned.

Mr. Hemming requested that Dr. Hugh Woods should be the next witness on the ground that he had undertaken to present himself for examination at the last Session.—The Legal Assessor pointed out that this was when Dr. Woods was conducting his own case, and that Mr. Neilsen must be allowed to conduct his case in his own way.

Mr. Neilsen then again called Mrs. Murphy as a witness and examined her; she was cross-examined by Mr. Hemming, and re-examined by Mr. Neilsen. No member of the Council desired to put any questions to the witness.

Mr. Neilsen called Mrs. Elizabeth Sarah Flora Rednall as a witness and examined her. She was cross-examined by Mr. Hemming. Mr. Neilsen did not desire to re-examine Mrs. Rednall, nor did any member of the Council desire to put a question to her, through the Chair.

Mr. Neilsen then called Miss Edith Ross, a nurse, and examined her. Miss Ross was cross-examined by Mr. Hemming.

Mr. Neilsen did not re-examine the witness, nor did any member of the Council ask her any questions, through the chair.

Mr. Neilsen called Mrs. Florence Robinson as a witness, and examined her. She was cross-examined by Mr. Hemming, and answered questions put to her by the Legal Assessor.

Moved by Dr. Norman Moore, seconded by Mr. Thomson, and agreed to:—"That Standing Order IV., 2, be suspended in order that the Council may meet on Saturday at 11 a.m., and sit till 4 p.m., with an interval from 1 to 2."

After Mr. Hemming had completed his cross-examination of the witness, the Council adjourned.

FIFTH DAY.—Saturday, May 30th, 1908.

The President, Dr. MacAlister, in the Chair.

The minutes of the previous meeting were read, amended, and confirmed. The whole time of the meeting (11 to 1, 2 to 4) was taken up by the consideration of the case of John Papa Nicolas, adjourned from the previous day.

Mrs. Adah Edney was called, and examined by Mr. Neilsen. Her evidence was principally to the effect of Mr. Nicolas having called on her without being sent for, and having mentioned that his fees were smaller than those of Mr. Atkinson.

The witness was cross-examined by Mr. Hemming, mostly with reference to her statutory declaration, and then re-examined by Mr. Neilsen.

Mrs. Susan Hart was called, and examined by Mr. Neilsen with reference to Mr. Nicolas having said that Mr. Atkinson was too old, and of the old school in the treatment of babies, and of having extolled his (Mr. Nicolas's) success in such cases.

Mr. Hemming cross-examined, and Mr. Neilsen re-examined the witness.

Mr. Lawrence Fielder Hemmans, M.B., B.S.Durh., F.R.C.S.Edin., was called, and examined by Mr. Neilsen on a question of partnership. The witness was cross-examined by Mr. Hemming, chiefly with reference to his (Mr. Hemmans') acquaintance with Mr. Nicolas. The witness also answered questions put to him by the Legal Assessor.

Mrs. Emily Bowles was called, and examined by Mr. Neilsen, principally with reference to what Mr. Nicolas had said to her about Mr. Atkinson's medical treatment of her child. The witness was cross-examined by Mr. Hemming.

Mrs. Kate Shepherd was called, and examined by Mr. Neilsen on the same points as the previous witness. She was cross-examined by Mr. Hemming, re-examined by Mr. Neilsen, and answered a question put to her by the Legal Assessor.

Mr. Lawrence, Mr. Atkinson's partner since 1907, was next called and examined by Mr. Neilsen, chiefly with reference to the statutory declarations which had been signed in his presence when he accompanied Mr. Pouter, the Commissioner of Oaths. Mr. Lawrence stated in his evidence that the declarations had always been deliberately read without undue haste to the witnesses before they had signed, and he considered that the witnesses had invariably understood what they signed. The witness was severely cross-examined by Mr. Hemming, the Legal Assessor having to interfere more than once. He was re-examined by Mr. Neilsen.

Mr. Henry Pouter, solicitor and Commissioner of Oaths, was called and examined by Mr. Neilsen, principally as to the method employed in taking the declarations. The witness was cross-examined by Mr. Hemming, and re-examined by Mr. Neilsen, and also answered a question put by the Legal Assessor.

Mrs. Alice Margaret Jacon and Mrs. Ruth Wicks were called, and examined by Mr. Neilsen, and cross-examined by Mr. Hemming, with reference to Mr. Nicolas's canvassing, and disparaging remarks about Mr. Atkinson.

Mr. Neilsen then stated that, as he had now called 13 out of 24 witnesses, he proposed to close his case, but he offered Dr. H. Woods for cross-examination.—After a few remarks from the Legal Assessor *re* the calling of Dr. Woods for cross-examination, as Mr. Hemming insisted on calling the witness, Dr. Woods entered the box and was cross-examined by Mr. Hemming chiefly with regard to Dr. Woods having visited some of the witnesses.

Mr. Hemming made a few remarks, in which he said he considered there was no case against his client, as systematic canvassing in Catford had not been shown, and the law of the Council under which Mr. Nicolas had been summoned included advertising and canvassing, the one excluding the other.

The Legal Assessor pointed out that this was not a law, but a warning.

Mr. Hemming then called and examined Mrs. Lily Pumpfleet with reference to what had been said about Mr. Nicolas's canvassing at Catford.—Mr. Neilsen did not cross-examine.

Mr. Lewis Dysart Bellman, a chemist's assistant, was called and examined by Mr. Hemming.—No cross-examination.

Mr. Hemming then offered himself as a witness, and was examined by his clerk, chiefly with regard to Mr. Nicolas's skill as a medical man.—Mr. Neilsen briefly cross-examined.

Mr. Nicolas then went into the witness-box, but as it was a few minutes to 4, Dr. Saundby proposed, and Mr. Langley Browne seconded, "That the Council should meet on Monday at 11." The motion, however, on being put, was lost by a large majority. The examination of Mr. Nicolas by Mr. Hemming had only just begun, when the Council adjourned.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held Friday, May 8th, 1908.

The President, A. R. Parsons, M.D., in the Chair.

HODGKIN'S DISEASE.

Dr. F. C. Purser showed the organs of a patient who had been under the care of Dr. Travers Smith, suffering from Hodgkin's disease. The glandular enlargement had been general, the tonsillar enlargement having led to very urgent symptoms. The blood count had shown generally 2,500,000 red cells and 12,000—21,000 white cells, with a high percentage (41—48) of lymphocytes. The latest count, made a fortnight before death, showed 12,500 white cells, 41 per cent. being lymphocytes. The case was further interesting in that he was first seen five years ago with typical primary and secondary syphilitic lesions, and there was a most definite history of the same symptoms 27 years previously. At the time of his death the patient was 53 years old. The pleural cavities and abdomen were full of fluid. The right lung was partly collapsed; both were œdematous. The pleuræ were extensively infiltrated with lymphoid cells. There was no infiltration of the lung parenchyma. The heart was a marked example of brown atrophy. The liver on the surface was almost typical of atrophic cirrhosis, though no interstitial inflammation could be detected on section. The nodules on the surface were composed of masses of lymphoid cells, which also infiltrated Glisson's capsule and the interlobular capillaries. There was little or no overgrowth of fibrous tissue. The spleen was described as three times its normal size, it was soft, but not otherwise remarkable. Though no lymphatic glands had been found enlarged in the thorax, the abdominal aorta was sheathed several layers deep in lymphatic glands, which had lost all typical structure, and were in many cases welded together; into some hæmorrhage had occurred. One nearly occluded the portal vein and explained the ascites, which had been latterly a very urgent symptom. No organ had undergone fatty or amyloid change.

Dr. **TRAVERS SMITH** said the case was interesting as that of a man who had acquired syphilis on two occasions with an interval of 27 years. There was more evidence than Dr. Purser had mentioned that the first attack was genuine syphilis, for he had had a condition of partial blindness after the first attack, which Dr. Joyce considered to be due to an indubitable attack of previous syphilis. The enlargement of his tonsils and retro-pharyngeal adenoid tissue was so great at one time on the last occasion that it led almost to his death from asphyxia. There was great enlargement of his spleen and liver on his last admission to hospital, and he had no doubt that both they and the superficial glands became smaller before he died, though he would be inclined to think that his abdominal glands became larger. He inclined to the diagnosis of Hodgkin's disease, rather than lymphatic leukæmia, both of which gradated into one another.

The **SECRETARY** said it was difficult to understand from the specimens under the microscope how there were only a normal number of leucocytes or lymphocytes in the circulating blood. All the sections were like those seen in lymphatic leukæmia and many of them were markedly infiltrated with white cells. The character of the infiltration in the liver was exactly what was seen in lymphatic and other leukæmias, and was fairly uniform in the respect that all the portal spaces were infiltrated with cells. The kidney was also infiltrated fairly generally, not, perhaps, to such a profound degree as one saw in very marked cases. He had seen cases of undoubted Hodgkin's disease in which they did not get similar infiltration, and he had not seen any in which the lymphatic glands themselves were so like lymphoid tissue as in the case before them.

Dr. **WIGHAM** said he had often noticed in lymphatic leukæmia that the smaller the vessels the more lymphocytes seemed to be got in them. In the larger vessels a large proportion of lymphocytes would be found, and in the large veins they would often find that the blood was very little different from normal. It was quite possible that in a case which was not very severe they might find plugs in the capillaries, and the blood as a whole showing very little increase of lymphocytes. It seemed to him impossible to draw a distinction between the two diseases, and the case might be one of lymphatic leukæmia with practically no leukæmia, and he wondered if a large increase of lymphocytes in the blood was really an essential sign of lymphatic leukæmia.

Dr. **STOKES** inquired as to what was the actual cause of death.

The **PRESIDENT** recalled a case of Hodgkin's disease in which exactly the same thing happened as in Dr. Purser's case as regards the subsiding of the glands. There was no improvement in the patient's general condition, and he got progressively weaker, with uncontrollable diarrhœa and passage of blood-stained mucus, and finally he succumbed. He had seen him in the earlier stages, and there was no material increase found in the number of white blood-cells.

Dr. **PURSER**, in reply, said the most marked symptom presented by the patient was dyspnœa. The lungs were everywhere œdematous, and there was considerable fluid in the pleural cavities. There was marked ascites, and the man died gradually, though quickly. The two diseases seemed to be the same, except that in one case the blood helped them to label it one way or the other, and it was quite conceivable that the formation of lymphoid tissue went on and the cells did not escape into the blood. The blood seemed to him to be simply a channel of communication between the tissues, and was not responsible for the number of leucocytes carried round.

SPINAL ABNORMALITY.

Dr. **HARVEY** said the patient, a girl, æt. 17, came to Dr. Gunn's dispensary at the Adelaide Hospital, complaining of pain in the back for the last two months. She was engaged in collar-making, and the pain only came on after prolonged stooping over her machine. Her father had, however, noticed some three months previously that she held her right shoulder higher than the left. Patient herself, however, believed that she had never had a straight back. The pain complained of did not seem to be very acute, nor did ordinary physical methods of examination cause any distress. The case appeared to be an ordinary lateral curvature, but an X-ray taken of patient's spine showed an irregularity in the vertebral bodies which led me to make the erroneous diagnosis of caries of the dorsal vertebræ. More careful examination of the negative, however, showed that there were only eleven ribs on the left side, and that the left side of the fourth dorsal vertebra was also absent. The case, then, seems to be one of failure to develop the left side of the fourth dorsal vertebra, with total absence of the corresponding rib on the same side.

Professor **DIXON** said the specimen described was one of extreme anatomical interest and also of extreme rarity. The rarity might be gauged from the fact that whenever the condition was alluded to, practically always the same two cases as Dr. Harvey quoted were mentioned. They were extremely fortunate in being able to see such a specimen.

PATHOLOGICAL REPORT OF ROTUNDA HOSPITAL.

Dr. **ROWLETTE** read the Pathological Report of the Rotunda Hospital for the year ending October 31st, 1907. He gave particulars of post-mortem examinations on the bodies of nine adult patients. In one case the *micrococcus rheumaticus* had been obtained in pure culture from the heart valves of a patient dying of acute rheumatism. Two fatal cases of pneumococcus peritonitis had occurred in the gynæcological department, and in each case with infected ovarian cysts. Three fatal cases of puerperal streptococcus infection occurred. Particulars were given of the examinations of curettings and of the different varieties of endometritis encountered. Particulars were given of the various operation specimens examined and of the various bacteria occurring in morbid puerperal cases.

Dr. **HASTINGS TWEEDY** expressed his gratitude for the admirable work done by Dr. Rowlette in the Rotunda Hospital, and for his excellent report, which would add enormously to the value of the hospital as a teaching centre.

The **SECRETARY** referred to a case of abdominal operation where the patient died suddenly two days afterwards, and there was no naked eye evidence as to the cause of death. The post-mortem finding of any practical value was microscopic and in the heart, which exhibited an extreme degree of segmentation with fragmentation of the muscle fibres. It was possible that a similar condition might be found in other cases of the same kind.

HYDRONEPHROSIS.

Dr. **Gunn** read a short paper on the above, and exhibited several specimens.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

Meeting held May 16th and 17th, 1908, at Harrogate.

The President, Dr. W. J. Tyson, F.R.C.P., J.P. (Folkestone), in the Chair.

About 135 Fellows and guests attended this meeting, which proved most instructive and successful. The fact is now firmly established that provincial meetings are very popular with the Fellows of the Society, and are much appreciated.

The Fellows were received at 3.15 p.m. in the Spa Room of the Royal Baths by the Mayor (Dr. Neville Williams), the Chairman of the Baths and Wells Committee (Alderman Milner, J.P.), the Town Clerk, Dr. Mouillot (the Provincial Secretary of the Society), and by Dr. Solly, the President-elect.

Eight new candidates were elected, which makes the total roll over 400.

The proceedings were opened by the Mayor of Harrogate, Dr. Neville Williams, after which the President, Dr. Tyson, took the chair. Mr. C. Fox **Strangways** then read a most interesting paper on "The Geology of Harrogate in Relation to its Mineral Waters," which was followed by a paper by Dr. **Frederick Lever**, President of the Harrogate Medical Society, on "The Harrogate Waters and their Therapeutics."

Tea was then served in the Spa Room, and the members were escorted over the Royal Baths, the Pump Rooms, and the Bogs Field.

At 7 p.m. the Fellows and guests dined together at the Hotel Majestic. The toast of "The Town and Corporation and the Medical Profession of Harrogate" was proposed by the President, and responded to by the Mayor and by Dr. Edgecombe. The toast of "The British Balneological and Climatological Society" was proposed by Alderman Milner, J.P., Chairman of the Baths and Wells Committee, and was responded to by Dr. Bagshawe, Chairman of Council, and by Dr. Leonard Williams, Editor of the *Journal of Balneology and Climatology*. Dr. **Edgecombe**, in the course of his remarks, said the spas and watering-places of this country owed a debt of gratitude to the British Balneological and Climatological Society for the work they had done and are doing in driving home to the minds of the medical men of this country the fact that here in the British Isles we have spas of equal, if not superior value, to any of those abroad, and that many patients hitherto sent abroad can be equally well treated at a home resort. He also considered that those members of the profession who practise at health resorts are under a deep obligation to the Society for its work in helping to raise spa treatment from the slough of empiricism to the domain of rational and scientific therapeutics.

The Fellows were then entertained at a concert at the Kursaal. On the following day (Sunday, May 17th) 84 Fellows and guests proceeded to Ripon, where some of them attended a service at Ripon Cathedral. The Dean of Ripon preached a sermon, the subject being "The Pool of Bethesda."

After the service, Dr. Green, Medical Officer of Health for Ripon, conducted the Fellows over the Ripon Spa Baths, where Mr. Bower, the Mayor of Ripon, and Alderman Wells, Chairman of the Spa Committee, received the party. The Fellows were entertained to luncheon at the Spa Hotel by the proprietors. Afterwards a visit was made to Fountains Abbey, by permission of the Marquis of Ripon. On returning to Ripon, the Mayor entertained the party to tea at the Spa Hotel, and later the Fellows returned by train to Harrogate.

The arrangements throughout the whole meeting were most satisfactory, and the thanks of the Fellows are due to Dr. Mouillot (Harrogate), the Organising Secretary, and to Dr. Garrad (Secretary of the Medical Society of Harrogate), who carried out so completely the intentions and wishes of the medical profession of Harrogate and Ripon in extending such a hearty welcome to the Society.

THE MEDICAL DEFENCE UNION.

The annual general meeting of the above Society was held, by the courteous permission of the Committee of Management, at the Medical Institution, Hope Street, Liverpool, on Thursday, May 21st, Dr. Stamford Felce, M.R.C.P., the President, in the chair.

The President, in moving the adoption of the annual report, traced the history of the Union to the present time. He mentioned that the Union had to thank several well-known members of the profession in Liverpool, notably Dr. Carter, F.R.C.P., and Sir James Barr, F.R.C.P., for valuable help and assistance upon the Council. Mention was made of the disabilities of the present Medical Act, and a hope expressed that some day the protection against unqualified practice under an amended Medical Act would be equal to that afforded by the Veterinary Act.

The death of Dr. Dreschfeld was feelingly referred to. The rapid growth of the Union from 400 members in 1888 to over 7,000 in the present year was referred to as proving the absolute necessity for such organisation. It was a fact that no one could claim immunity from the attacks of unscrupulous patients, and without the assistance promptly and efficiently given by the Union, many a practitioner would be either ruined in pocket or harassed almost beyond endurance. It was a great relief to members to know that their cases were taken over by skilled officials, and the responsibilities removed from the individuals concerned to the broad shoulders of the Union itself. Reference was also made to the steps taken by the Union to stem the torrent of unqualified practice by raising actions for damages against quacks. This has been successful in several cases. It had been suggested that some scheme could be adopted by which the whole risk of adverse verdicts and damages should be taken over, but after serious consideration it was decided that it was not possible, and, further, that it would be against public and professional polity, and likely to lead to serious injury to the profession, if not to actions for champerty and maintenance.

A member called attention to the numerous instances of chemists prescribing and acting as medical practitioners, and the danger which led to infant mortality by such practice as it appeared to him.

The President said the matter should receive attention.

Three vacancies upon the Council were then filled up by the election of Mr. F. C. Larkin, F.R.C.S., and the two retiring members of the Council, Dr. Gunton Alderton and Dr. Messiter, J.P.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, May 31st, 1908.

MISTLETOE AS AN HYPOTENSOR.

In a recent *thèse* on the hypotensive action of viscum album, in arterio-sclerosis and Bright's disease, M. Vachez, without considering this agent as a panacea or sovereign remedy, believes that it is a useful adjunct to the therapeutical arsenal as an hypotensor in divers affections.

For a long time the medical world in France remained indifferent to the studies made on mistletoe abroad, but within the last few years attention has been brought to it by experiments made by Degny and Gaulthier, who found it effective in albuminuria and hæmoptysis, similar to nitrite of amyl. Viscum album arrests hæmoptysis by lowering the tension in the general circulation, producing depletion in the pulmonary circulation.

Nitrite of amyl, even in small doses, shows its vasodilating action on the peripheric circulation by producing a congestive state of the head, neck and chest in patients who take it. Nothing of the kind has been remarked in patients treated by the extract of mistletoe.

On the other hand, autopsy af animals submitted to toxic doses of the extract showed an intense congestion of the abdominal viscera, while the lungs, on the contrary, were pale and the heart empty.

The action of viscum album had no effect like that of nitrite of amyl on the peripheric circulation, but on the general circulation. Viscum album is, consequently a hypotensor by direct action on the vaso-constrictor and vaso-dilator centres by paralysing the former and stimulating the latter, it produces the vaso-dilatation and depression in the general circulation.

Arterial hypertension, says Prof. Huchard, is the cause of arterio-sclerosis, and the most frequent cause of arteritis by its action on the vascular walls.

The early treatment of arterial hypertension wards off such maladies as arterio-sclerosis, angina pectoris, and certain cardiac symptoms.

M. Vachez reports several typical cases treated by the mistletoe extract. In one case the tension was rapidly lowered after one or two injections, while dyspnœa and coincident nervous disturbance ceased.

In another case, presenting all the signs of uræmia, the vomiting ceased after the first injection, as well as the violent headaches from which the patient had suffered for some time previously.

A woman suffering from arterio-sclerosis and presenting the troubles inherent to the climacteric period, abundant epistaxis, headache, vapours, etc., was completely relieved from epistaxis after the first injection of viscum album, while the other symptoms disappeared with the lowering of the tension.

This treatment presents no inconvenience, the extract of mistletoe, being but slightly toxic, can be administered in large doses without danger.

Perhaps the pillular form is the best method of administration, as injections are painful and irritating. However, we give here the formula employed by M. Vachez:—

Watery extract of v. album, 4 grammes.
Chloride of sodium, 0.70 centigr.
Water, 100.

Thirty drops injected daily.

Stitch.

The vulgar term stitch in the side indicates a special thoracic pain, declaring itself as a symptom of certain acute pleuro-pulmonary affections, constituting an important factor of dyspnœa, because it increases with the amplitude of the respiratory movements so as to become intolerable.

Suddenly or gradually a patient is seized with an acute and spontaneous pain, localised either under the nipple or behind under the scapula, dull and continual or lancinating or fugitive, exasperated by cough, deep inspirations or movements of the trunk.

This special pain is due to irritation of several nerve filaments, sub-pleural, by reason of inflammation of the serous membrane covering them; it is consequently a symptom of pleuritis.

In acute pneumonia the stitch is felt at the very outset and its maximum of intensity is felt in the submammary region of the same side. It rarely persists beyond 48 hours. Its persistence beyond the sixth day, or its reappearance after defervescence, is almost always, says Prof. Barth, an indication of secondary pleurisy.

In the course of bronchitis, pain in the side, when it is not due to pleurodynia provoked by the effort of coughing, is generally symptomatic of bronchopneumonia propagated to the cortical layer of the lung.

Pneumothorax, especially in its septic forms, is announced suddenly by intense pain, cutting like a knife and paralysing the movements of the thorax; the dyspnœa is excessive.

In sero-fibrinous pleurisy, the stitch is rarely absent, it is generally dull, but exasperated by the cough; it disappears when the effusion has separated the two coverings of the pleura, and is replaced by a vague sensation of tension when by the increase of the liquid the lung is compressed, displacing the neighbouring organs.

In purulent pleurisies, the pain is excessively violent, irritation of the terminal filaments of the phrenic nerve, it is localised over the false ribs, and pressure in this part provokes almost phenomena of suffocation.

In purulent pleurises, the pain is excessively violent, the slightest pressure over the point provoking great suffering.

Consumptive patients suffer frequently from dull pains seated at the apex of the lungs or beneath the scapulæ, which they attribute to rheumatism, but in reality they are due to dry pleurisy.

GERMANY.

Berlin, May 31st, 1908.

At the last meeting of the Medical Society, Hr. B. Fraenkel discussed

The Reduced Mortality from Tuberculosis, and its Causes.

He said that from a large array of statistical material it had been shown that since the year 1887 the mortality from tuberculosis, which up to that year had for several years maintained a uniform level, had been steadily diminishing. This diminution had been less considerable in the country than in the towns. It had been greater in the western parts of the monarchy than in the eastern. Two extraordinarily important factors in the history of tuberculosis were contemporaneous with this reduction: the discovery of the tubercle bacillus by Robert Koch in 1882, and the establishment of sick clubs. Hand-in-hand with this was an undeniable improvement in the social position of the working classes and of their mode of life. Statistical observations in Great Britain showed that social position was an important factor. In England and Scotland the mortality curve of tuberculosis ran parallel with our own. In Ireland it was almost at the same height as it was 20 years ago. The only reason for this could be that social distress had diminished but little or not at all in comparison with the two other countries. At the same time it showed the virulence of the bacillus had not diminished, nor had the resisting power of the individual increased from custom or any other cause, but that factors played a part that were not independent of the human will—namely, improvement of the mode of life.

The objection that the discovery of the tubercle bacillus had refined the diagnosis, and that it was given as the cause of death more rarely than formerly, did not hold, as statistics showed that during the same period the number of other diseases of the respiratory tract had not increased. We were, however, indebted to our knowledge of the importance of the tubercle bacillus and of the nature of tubercle for a possible rational campaign against this disease of the people—the principles of it, the disinfection of sputum, early diagnosis, isolation of the patient, and, together with all this, the campaign against bovine tuberculosis and inspection of meat.

The speaker then passed on to the importance of curative resorts, shown by the fact that from 1900 to 1906 the number of workmen invalided gradually diminished, as a major part were cured. Along with this importance for the individual patient, these institutions were of great importance for the community at large, for it was not a matter of indifference that about 40,000 sick people were isolated for three months, and about 6,000 bacillus expectorants a year lost their bacilli and ceased to be a source of danger to the public.

The *Deutsche Med. Zeitung*, 39, gives a *résumé* of a case of

Late Changes in the Peritoneum after Perforative Peritonitis in Consequence of Spontaneous Recovery from Gunshot Wound of the Intestines.

A soldier who had received a gunshot wound of the abdomen in the Russo-Japanese war, from that time suffered from repeated attacks of abdominal pain, occurring especially after partaking of food that was indigestible. Fourteen months after receipt of the injury an operation was performed, at which it was found that cicatricial bands were present, one of which united two portions of intestinal wall and was hollow within. It corresponded in situation to the cicatrised intestinal wound. Besides this, a number of sub-serous "tubercles" were found, some of which were removed for microscopical examination. The bands were resected, and the patient recovered. At the examination of the "tubercles" it was found that vegetable remains were present in them, surrounded by collections of giant, mononuclear, and polynuclear cells, the mononuclear cells predominating, of the type of the fibroblasts and polyblasts. The case was therefore an example of encapsulisation of extruded intestinal contents, with pseudo-tuberculous changes in the peritoneum. Such cases were very rare. On the other hand, the case showed that such so-called recoveries after injuries of intestines that had been treated expectantly were really no recoveries at all, and occasionally rendered a subsequent operation necessary.

AUSTRIA.

Vienna, May 31st, 1908.

Toxine of Fatigue.

At the Gesellschaft f. Innere Medizin, Gellhorn gave a history of his experiments with "keno-toxine," "anti-keno-toxins," and "keno-precipitine," all of which are closely connected with the fatigued muscle. "Keno-toxine" is obtained from the muscles of exhausted animals by pressure after death, while the antitoxine is got from the serum of another animal that has been immunised. This potent substance can also be obtained from albumin, chemically, by shaking at a temperature under 40° Centigrade, and the antitoxine at boiling point. It appears that the first transition is from the antitoxine precipitate or keno-precipitine, as Gellhorn is pleased to call it, which does not act on native albumin, but on other forms is potent. In the urine of men at rest, none, or a trace of the precipitine may be discovered, but in the urine of the exhausted it is met with in abundance. It is also found in the breath of those suffering from bacterial poisoning, as well as in the excretions of the febrile. He therefore found no keno-toxine in healthy infants, but met with it in large quantities in febrile conditions, which disappeared on the child regaining health.

Function of the Thymus Gland.

Sommer gave a description of his experiments with young animals not exceeding 14 days old and principally confined to cats and dogs. In some cases he extirpated the thymus gland, in others transplanted it in order to demonstrate its effect on the organism. Without exception, thymectomy of the cat brought about an intercurrent disease in two months after the operation that led to death. In the case of transplantation, six or seven months sufficed after thymectomy. After the operation the animal usually became plump and unable to walk, while the hair was rough and dry. His Röntgen photographs of sections of the long bones showed that after the thymectomy they became shorter and thicker than the bones of the control animal, while the bones of the transplanted thymus became longer. Microscopically, he found changes in the other organs which were difficult to analyse at the present time.

Senile Chorea.

Weygandt showed a patient who suffered from convulsive cough and inco-ordinate movements in the muscles of the extremities. Nothing could be seen in larynx or found in the chest to account for the uncontrollable cough. He thought the prognosis was bad, and the case hopeless, and attributed the convulsive movements to an arterial sclerosis of the cerebral vascular system.

Pure Treatment.

Stumpf again brought forward his favourite subject of the "Bolus Alba" as the most essential principle in the treatment of all diseases. His theory is that all treatment should be anti-bacterial, both food and medicine, as in surgical cases. Cholera, diphtheria, and puerperal fever readily yield to this form of treatment, which he considers the correct method.

Narcosis of the Arabians.

Moeller tells us that in 704 A.D. the Arabians made use of cannabis indica and opium for relieving pain in operations. There was also a pulverised stone of Memphis which was dissolved in acetic acid, producing a narcotic that we seem to know nothing of. From the Greeks they obtained "mandragora" and "alraun" root for producing anæsthesia, but their pharmacology must have been bad, as out of 712 treated 704 died. Urwa was called in to the Kalif, who seems to have suffered from gangrene in the right foot, and decided that the foot must come off, which the Kalif declined. Urwa avowed that he would die if the swelling rose to the knee. Consent was obtained, but the Kalif would take no drug, saying he was no Boor and required no such preparation. He suffered the operation without wincing, and lived eight years thereafter, although another operation had to be performed, probably for sloughing.

Some assume that taumelboch, lolium temululentum was the most likely narcotic used. Another solution produces a powerful narcotic of lolium, which induces vomiting tremor, altered vision, vertigo, and loss of consciousness. Such were the narcoses of 704.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Munificent Gift to the Aberdeen Royal Infirmary.—Lord Mountstephen, to whose generosity the Infirmary has in the past owed so many donations, has forwarded to the managers of the institution a draft for £26,738. In a letter accompanying his munificent gift, Lord Mountstephen says that he had intended to transfer the sum to the investment fund of the Infirmary, but that he has come to the conclusion that it will be more usefully spent on permanent improvements than on providing a permanent increase of income. The letter concludes: It would be little short of a calamity if what I have done for the hospital should have the effect of weakening the interest of the people of Aberdeen in the old Infirmary, in which I was a patient sixty-two years ago.

Edinburgh University Lord Rectorship.—For the first time in a number of years there is a likelihood that the nominee for this post will be selected on a non-political basis. The two party names suggested were those of Mr. Winston Churchill and Mr. George Wyndham, but after some discussion at a meeting of the students last week the idea of a non-political Lord Rector found general favour. The names proposed are both those of men eminent in the medical profession, namely, Professor Crum Brown, whose resignation of the chemistry chair was announced in these columns a few weeks ago, and Professor Osler, Oxford. It was ultimately decided to approach Professor Crum Brown on the subject. There is much to be said both for and against a political Lord Rector, but one thing at least seems desirable, that the candidate chosen should be of distinction from an academic as well as a party point of view, and in the circumstances it seems that the students are well advised in choosing as their nominee one who ranks second to none in intellectual attainments.

Medical Officer of Health for Edinburgh.—Applications have been sent in by the twelve gentlemen whose names follow. The salary is not less than £800 per annum. G. E. Brooke, M.A., L.R.C.P., Bath; John Brownlee, M.D., D.Sc., Superintendent to the Glasgow Fever Hospital, Belvedere; J. J. Buchan, M.D., M.O.H. for St. Helens; J. H. Garret, M.D., M.O.H., Cheltenham; J. H. Jones, M.D., D.Sc., M.O.H. for Newport, Mon.; Lloyd Roberts, M.D., M.O.H. to a number of Urban and Rural Councils in Wales; R. S. Marsden, M.B., Public Health Department, Birkenhead; H. C. Pattin, M.D. Norwich; Alex. Robb, M.A., M.D., M.O.H., Paisley; Wm. Robertson, M.D., M.O.H., Leith; A. M. Williamson, M.D., Chief Sanitary Inspector, Edinburgh; William Wright, M.D., Deputy M.O.H., Glasgow.

BELFAST.

The Report of the Belfast Health Commission.—A curious situation has arisen in connection with the report of the Viceregal Commission which sat last year to inquire into the alleged excessive death-rate of Belfast. The report, after a very long delay, was published a few weeks ago, and naturally all interested parties wished to procure copies, but the greatest difficulty was experienced in obtaining them. It now appears that only 200 copies were printed, the work being done at the expense of the Belfast Corporation. Of these, 150 copies were taken by the Local Government Board to give to various public bodies, and now no copies can be had. The Corporation objects to the expense of printing more, and there is no power to compel them to do so. Meantime, the Belfast Water Commissioners are complaining loudly, for the report deals particularly with the water supply, and naturally they wish to read and digest it before discussing the matter. The only practical outcome of the report so far seems to be an active crusade against the cockle gatherers of Belfast Lough, who are supposed to be more or less responsible for the typhoid which is always present. But in spite of the crusade, 15 cases of typhoid were notified during the last fortnight.

The Corporation and Tuberculosis.—Reference has been made in this column on several occasions to the arrangement made between the Corporation and the authorities of the Forster Green Hospital, under which 25 beds are to be provided and maintained by the hospital for patients nominated and paid for by the Corporation, the arrangement to be binding for 10 years. The preparations for this extension of the Forster Green Hospital are proceeding actively, and meantime the agreement has been extended to include 10 more beds, making a total of 35 extra beds to be provided. The arrangement seems an excellent one, and much better than the starting of a new sanatorium by the Corporation. One difficulty has arisen, and is at present being considered by the local medical societies at the request of the medical staff of the hospital, and that is the position of the members of that staff as regards these municipal patients. The staff is an honorary one, but it seems very doubtful if it is wise that they should give their services free for the treatment of these new rate-paid patients, when their colleagues at the Union Infirmary are paid for attending the rate-paid patients in the Whiteabbey Sanatorium. The matter rests with the Board of Management of the Forster Green Hospital and not with the Corporation, as the terms of the agreement are that the payment of a certain sum per week is to cover all charges.

LETTERS TO THE EDITOR.

CHARGES IN NURSING HOMES.

To the Editor of The Medical Press and Circular.

Sir,—The exorbitant charges made by nursing homes has been brought to my notice several times, but the question may well be asked are there no medical men (or medical women) behind the back of the nursing home manager who poses as proprietor? From what I know "goes on" in the metropolis I have my doubts. All concerned with nursing homes expect a "pinch" out of the profits made from the unfortunate patient, who, in some cases, is recommended by the medical attendant to go to the nursing home in which *he* naturally takes an "interest." I have been in a wretched bedroom, at the top of a large house, where the patient paid five guineas per week. Hardly any furniture (patient recovering from operation) and food principally milk and Bovril! The sooner some nursing homes are found out by the public the better.

I am, Sir, yours truly,
Alex. Duke.

London, W.

THE POPULATION QUESTION.

To the Editor of The Medical Press and Circular.

Sir,—It would seem strange, indeed, had it not occurred at the commemorative period of Empire celebration, that this opportunity should not be seized upon as a pretext for pessimists given to the shedding of tears (be they medical officers of health, prelates, or political economists) to relieve themselves on the grievance of a declining birth-rate. May I be allowed, therefore, to indulge in one or two platitudes which "Surrey Doctor" and others may do well to grasp?

In the first place, as all will admit, the declining birth-rate is limited or confined to certain portions of the globe (amongst which ours is one). In other words, no depopulation is going on in the world at large, as the Census of the present compared to any past generation clearly indicates. The injunction, therefore, "Be fruitful and multiply," is being consummated at somebody's expense. It is obvious that in the animal economy there will, in the process of time, at the present ratio of increase, be no more room for extension of the human race; hence either plague, pestilence, war, or famine must deplete the earth; otherwise, artificial means of stemming the tide of overflowing population will inevitably be resorted to at some future date. Why, therefore, should a handful of squeamish folk, themselves, no doubt, comfortably provided for, belie their less fortunate brethren for working out their present and own salvation.

It is often urged that the decrease of population is indicative of national decadence. This *may* be so. On the other hand, there is no evidence forthcoming to decide that a decline of birth-rate is not rather the effect than the cause of racial decadence. Assuming, however, for argument's sake, that a continuous and low birth-rate may be the cause of national decay, again, what evidence is there to show that an unwieldy surplus population may not (through rearing in semi-starvation, over-crowding, and otherwise unhealthy conditions) conduce to disease and premature death, and hence destroy the sinews of a race far more expeditiously than a declining or stationary birth-rate?

It is wildly presumptive to conclude that the game of Empire-building (the supposed safety-valve or receptacle for our redundant population) will always prove a paying game. Few, indeed, seem to grasp the fact that the British Empire has developed and been born out of British resources. The British nation is the nucleus and core of our Empire, and if the core become rotten or decayed, the Empire would assuredly sooner or later disintegrate, much as a tree or plant must perish from decay of its root, because when the Colonies and other British possessions have extracted our best blood, as they are encouraged to do, and, indeed, insist upon doing during the selection of emigrants, and so by degrees reducing the British nation to a shrivelled, half-starved and decrepit race (and we are constantly reminded there are twelve millions already on the verge of starvation), our Colonies will no longer respect the Mother Country, but rather feel ashamed of us, and will become patriotic amongst themselves, a dissolution of partnership will probably next take place, and we shall be left, as concerns our Empire, isolated and alone on the high seas.

I am, Sir, yours truly,
Clement H. Sers.

Brighton, May 28th, 1908.

A METHOD IN MADNESS.

To the Editor of The Medical Press and Circular.

Sir,—It is, as you say, "mere hooliganism, and quite inexcusable under any circumstances," for Miss Elizabeth Knight, M.B., and her friends to demonstrate on the Prime Minister's doorstep. It is a question, however, whether such conduct should be dealt with by the General Medical Council, since presumably the lady was there *qua* Elizabeth Knight, and not *qua* M.B. Moreover, since she is suffering at Holloway a penalty deemed by a wise magistrate to fit the crime, it would hardly be fair to punish her over again for the same offence. The other medical lady, having escaped the police, should doubtless be summarily dealt with by the General Medical Council, but unfortunately her identity is unknown.

On the more general question, however, of the methods of the active women suffragists, there are some points we are inclined in our disgust to forget. Are these demonstrations mere outburst of hysteria, mere hooliganism, mere naughtiness, or is there really a method in the madness? So far the policy of virile agitation—if I may use the adjective—seems to have roused little but feelings of disgust. No cause can be good, it is felt, which can make use of such unreasonable methods. This would be a perfect answer to the suffragists if mankind were only swayed by motives of reason. We English, however, are an eminently practical people. We pay attention to the obvious matter of fact, and are quite content to do without appeals to reason. In fact, no reform could be gained among us, were there nothing but *arguments* in its favour. In the history of the last century, social reforms were gained, not because they were felt to be reasonable, but because a party rose to demand them strong enough to make its will felt. Mr. Gladstone entered on his Irish Land policy, not because he thought land reform in Ireland reasonable and right, but, as he admitted, to avert revolution. Irish Land Reform went on, not because it was reasonable and right, but because landlords were shot in Ireland, and Mr. Parnell made government impossible at Westminster. The Education Bill of 1902 has become impossible, not directly because of any injustice in it, but because men went to gaol rather than obey it. The women suffragists have learnt the lesson. The policy of outrage, of breaking the law, of making one's self a nuisance to people, is the way to get what one wants. Being tender-hearted and still somewhat scrupulous their measures are rather half-hearted and so far ineffective. Their methods are doubtless inexcusable, shocking, immoral, but they are the methods which have led other reforms to success. We are an eminently practical people, and we will soon find that it will be much less trouble to give these women what they want than to continue sending them to gaol. They will then get what they want.

I am, Sir, yours truly,
CRITICUS.

Dublin, May 27th, 1908.

[We fear our correspondent's letter trenches on dangerous ground. Our only concern is for the good name of the profession, which we consider to be tarnished by members who behave in the manner described.—ED.]

THE ST. GEORGE'S NAUHEIM INSTITUTE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There have recently appeared in the lay press notices relating to an injunction which was, by consent, granted against this Institute at the suit of the Hessian Government. As such notices in their abbreviated form, and in the absence of an explanation, are calculated to cause an entirely erroneous impression regarding an Institution of which, in conjunction with my colleague, Dr. Hill, I am in charge, I ask of your courtesy to insert this letter in your widely read paper.

This Institute has been under my control for the past few months, and whilst disclaiming any responsibility for the action of the directors before my connection with the Institute, I feel that it is due both to my colleague, myself, and those of my profession who have so cordially supported me, that an explanation of the very misleading paragraphs that have appeared in the leading daily journals should be given. The injunction was, *inter alia,* to restrain the St. George's Nauheim Institute from representing that they were the agents of the Hessian Government, from using the Hessian Arms, from representing their business as a branch of the Government, and from using the name Nauheim without clearly distinguishing the baths of the Institute from those of the Government. From the fact that the injunction was consented to, it might be inferred that the St. George's Institute had wrongfully committed all these acts, but as a matter of fact Mr. Cozens-Hardy, who represented this Institute at the trial, particularly repudiated such a state of affairs, and agreed to the injunction because it necessitated absolutely no change in any detail whatsoever in the present conduct of the Institute.

From the correspondence that I have seen it would appear that the Institute were warranted in using the Hessian Arms, and announcing themselves as by appointment agents for the State Springs of Bad Nauheim, because a gentleman, a Mr. Ed. Schmidt, of Berlin, writing on the official Government paper, and obviously an accredited agent of the Hessian Government, had specifically informed the Directors of the Institute that they had the right to do so, and as a matter of fact the Institution are the sole agents in Great Britain for the sale of the waters bottled under Government supervision at the State Springs. When, as far back as November 2nd last year, the Hessian authorities wrote asking for information concerning the acts of which they now complain, a letter was sent in reply giving the information asked for, and offering to remove these notices should such removal be insisted on, the courtesy of a reply was not extended, and two months later, viz., on December 29th, a writ was issued, and after several months further delay on the part of the Hessian Government a statement of claim was served.

Mr. McNaughton, K.C., on behalf of the Hessian Government, stated that the Directors of the St. George's Institute had claimed that the Nauheim system can cure every malady that flesh is heir to. Although in no way connected with, or responsible for the statements referred to, I should like to point out that the list of ailments published by the Directors of the Institute is identical with that published by the Society of Physicians at Bad Nauheim in their prospectus, so that it would appear that the Hessian authorities are complaining of the act of their own Society of Physicians. Personally, I think most medical men will agree with me in supporting the Hessian Government in their condemnation of this extraordinarily prolific list of diseases. At all events, since taking charge of the Institute, I have very much curtailed the list of indications.

As for many months past the Institution has been conducted on methods above reproach, and approved by many of the leading physicians and medical journals, the action of the Hessian Government seems to bear only one construction, viz., an attempt to throw odium upon an Institute, which though at present in its infancy, is likely in the future to reduce the income which the town of Bad Nauheim now draws at the expense of English visitors, and of the English medical profession. In other words, the Bad Nauheim authorities are intolerant of any attempt to encroach upon what they regard as their monopoly, but if anything could conduce to an end which they least desire, it will be found in the high-handed and narrow-minded procedure in which they have indulged.

Trusting that I have not encroached too much on your patience and space,

I am, Sir, yours truly,
WM. BAIN, M.B., B.Sc.

OBITUARY.

DR. McCALMAN, OF OBAN.

WE regret to announce the death, on May 25th, of Dr. Dove McCalman, a very well-known practitioner in the West Highlands. He was in his sixty-fifth year, and had been in practice in Oban for twenty years. Holding no public appointments, he was instrumental in founding the West Highland Cottage Hospital at Oban, which has proved an immense boon to the population of the district. He was medical superintendent of the hospital until a year or two ago, when reasons of health compelled his retirement.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Prolapse of the Female Urethra.—Barbour Simpson (*Surgery, Gynæcology, and Obstetrics*, May, 1908) describes the case of a multipara, æt. 56, who came under his care complaining of hæmorrhage and pain on micturition. The attacks of hæmorrhage came on at intervals and varied in severity. An attack which lasted for an hour made her seek treatment. Patient suffered from chronic constipation of a persistent type and had for some time past been in a feeble state of health, having had three attacks of nephritis in five years previous to seeking advice for the dysuria and hæmaturia. Examination revealed protruding from the urinary meatus a red mass the size of a large cherry, which proved to be the prolaped mucous membrane of the urethra, very congested and sensitive. Nothing abnormal was found on vaginal examination. Reduction under anæsthetic was tried, but failed. So the prolapsed mass was removed by scissors, the hæmorrhage being smart, and the mucous membrane united to mucous membrane round the urethral orifice and a dressing applied. In two days the patient could pass water for herself, and in ten days the part was healed. Microscopically, the mass removed was angiomatous in structure. The author points out that the condition has been ascribed to a sudden fall, or a large caruncle dragging on the mucous membrane, or the constant straining at stool coupled with general debility such as was found in the case reported. Cystitis and the presence of a calculus have been known to cause the condition. Kleinwächter has described two varieties of urethral prolapse, one in which the mucosa near orifice is excited, the other in which it becomes loosened higher up, gradually extending down until it appears at the meatus. Treatment for the mere excision with astringents after reduction may succeed, but in cases as described operative measures are nearly always necessary. H.

A Fatal Case of Inversion of the Uterus.—Gunn (*Brit. Med. Journal*, May 23rd, 1908) describes a case of this nature. Sent for by a certified midwife, on arrival was informed that the patient had fainted, but on seeing and examining the woman life was found already extinct. The following facts were gleaned:—The patient has been normally confined about six hours previously, the placenta following spontaneously in about half an hour. The patient afterwards was made comfortable, and the midwife then left. Some five hours later, having a desire to pass water, the patient was assisted on to her knees, and strained greatly in her efforts at micturition, with the result that "something else began to come away." The midwife was again sent for, and on arrival diagnosed the tumour which was presenting at the vulva as the head of a second child. As the patient was in an exhausted condition the doctor was sent for. Having ascertained that life was extinct he examined the patient, and found a flabby sac-shaped mass between the thighs larger than a large child's head, which proved to be the completely inverted uterus. The placental site appeared normal. The perinæum was badly torn in some previous labour and had failed to unite, leaving a gaping orifice. The patient was a vi-para, æt. 27. Dr. Gunn concludes that the straining at micturition while kneeling, coupled with a gaping vaginal orifice, was too much for a feeble non-contracting uterus, thus bringing about the condition, death being probably due to shock. H.

Preservation of the Ovaries Entire or in Part in Supravaginal or Panhysterectomy.—Reuben Peterson (*Amer. Jour. Obst.*, May, 1908).—The investigations upon which this paper is based were undertaken to determine if the preservation of more or less ovarian tissue after the removal of the uterus tended in any way to mitigate the discomforts arising from the artificially induced menopause. The conclusions arrived at were that at least 10 per cent. of all women regularly menstruating at the time of operation will be free from the troublesome symptoms of the artificial menopause after hysterectomy with removal of the ovaries; and the percentage of women with no symptoms after similar operations will be slightly more than doubled if some ovarian tissue be retained. The severity of the symptoms of the artificial menopause is much less when the ovaries are retained after hysterectomy, but it is not necessarily true that the younger the woman the more will she suffer from the symptoms of the menopause after hysterectomy with removal of the ovaries, as the greatest percentage of suffering was found in women operated on between 40 and 44. The frequency and severity of the artificial menopause is not influenced in any way by the kind of hysterectomy performed whether the ovaries are removed or retained, and the severity is the same after hysterectomies with removal of the ovaries for fibroid disease of the uterus and inflammatory disease of the appendages. Retention of ovarian tissue cuts short the period of suffering of the artificial menopause, and the greater the amount of ovarian tissue conserved, the more will the symptoms be mitigated. F.

Intra-Uterine Death of Fœtus in Six Consecutive Pregnancies.—Williamson and Holland (*Jour. of Obst. and Gyn.*, May, 1908).—The pathology of ante-natal death is obscure, and has been but little investigated. Syphilis is justly regarded as one of the commonest causes, and the following case demonstrates that even in the absence of a history of infection or of any clinical manifestations of the disease in the parents, syphilis may be responsible for the death of the child. A woman with a history of having consecutive still-born children, and again pregnant, presented herself for examination and treatment. The question of syphilitic infection was carefully inquired into, but with an absolutely negative result. Her husband was interviewed and carefully examined, and not a single fact, either in the history or clinical examination, which could be regarded as even suspicious was elicited. Neither the wife nor husband followed an injurious occupation. Before any treatment was administered, the woman was again delivered of a still-born child. The post-mortem notes are as follows:—Child premature; about 36 weeks' gestation; macerated, but not foul-smelling. Spirochæta pallida are distributed throughout the whole section of liver examined. Sections of spleen show spirochætes in some abundance, but no spirochætes could be detected in sections of umbilical cord, thus proving conclusively the presence of a syphilitic infection in the absence of clinical manifestations and in spite of a negative history. In her next pregnancy she was treated with mercury and iodide of potassium. Labour was induced, and the patient delivered of living twins. F.

The Abdominal Incision.—Collins (*Surg. Gyn. and Obst.*, April, 1908).—The writer advocates an abdominal incision which passes through both aponeuroses and muscle. The incision in the aponeurosis and the split in the muscle should run in different directions, and this can be done in a large number of abdominal operations. A longitudinal incision should not be made through the linea alba or the sheaths of the rectus, at a right angle to the combined pull of the three side muscles, when it is possible to avoid it. For very large tumours and cases where the character and location of the pathology is in doubt, the longitudinal incision is probably necessary, and if it is necessary the split in the rectus should not be continuous with the aponeurotic incision, but should be placed to one side, and preferably, through its inner half, to avoid the intercostal nerves which enter the outer half. F.

Use of Filigree in Infected Wounds of the Abdominal Wall.—Bartlett (*Surg. Gyn. and Obst.*, March, 1908).—The author strongly advocates the insertion of filigree in infected wounds of the abdominal wall, as a prophylactic measure against incisional hernia. It must be placed beneath the aponeurosis or a layer of muscle. The wound must be clothed in healthy granulations and free from pockets containing pus. In his five cases the healing of the wound was not interfered with by the filigree, and in no case had a hernia occurred after periods varying from two months to two years. F.

MEDICAL NEWS IN BRIEF

The Royal College of Surgeons in Ireland and the Universities Bill.

At the annual general meeting of the Fellows, held on Saturday last, May 30th, Sir Henry Swanzy, President, presiding, the report for the year was submitted and adopted. The following resolution was proposed by Sir Charles A. Cameron, C.B., and seconded by Prof. J. S. McArdle, and passed unanimously:—"That this College, while in no way desiring to interfere in the question of University education, view with alarm the consequences to the College which will be brought about by the establishment under the Irish Universities Bill now in Parliament of a State-endowed Medical School in connection with the proposed new University in Dublin; for it is to be anticipated that serious damage and loss will result to the unendowed school of this College, and therefore to the Royal College itself from that State-aided competition. That it is contrary not only to justice and fair play, but also to the public interest, that this College, established by Royal Charter, and its school, which for a century and a quarter have done great and important work for the State and the country, and which, if permitted, would be competent to continue that valuable work, should be crushed. That the College approve of the steps taken by the Council to bring its claim for a Government grant for its School to the notice of the Chief Secretary, and they hereby express their belief in the justice of that claim, and press it on the favourable consideration of the Government."

Sir Charles Cameron, as a Past President of the College and its Honorary Secretary, gave cogent reasons for the resolution standing in his name, with the subject of which we dealt fully in a "special article" last week. In seconding the resolution, Professor McArdle remarked that he was glad the resolution did not mention any of the three desires so frequently spoken of as dear to their hearts—viz.: (*a*) To be a constituent college of the new University; (*b*) to be an affiliated College; (*c*) to have representatives of the Senate of the new University. If the College became a constituent College, its Council would be no longer required, its individuality would be lost, the Senate would make appointments, direct the Courses, and, in fact, supplant the present managers of both College and School. If affiliation were accepted, nothing but the privilege of educating men for the new degrees would be attained, and as regarded representation on the Senate, that could be of no possible service to the College. He concluded by affirming that the Royal College of Surgeons had done, is doing, and would continue to do good and necessary work, and he therefore supported this resolution in the most whole-hearted way. Sir Lambert Ormsby and Mr. J. Lentaigne (Vice-President) having also spoken in favour of the resolution, the meeting concluded.

Scottish Diplomates' Association Dinner.

A very pleasant evening was spent on May 26th last by the members of the Scottish Medical Diplomates' Association and their guests on the occasion of the fourth annual dinner of the Society. A touch of novelty was given to the proceedings by holding the function at the Waldorf Hotel, and it may be said at once that the dinner from the gastronomic point of view was sufficient to please the most hardened gourmet. A good company assembled under the chairmanship of Dr. David Walsh, President of the Society, and after the knife-and-fork preliminaries, an excellent entertainment was provided in the intervals between the oratorical efforts of the speakers. The toast of the evening, "Success to the Association," was proposed by the President, who spoke feelingly about the disadvantages under which the diplomates of the Scottish Colleges laboured in England, and the efforts made by the Association to assert the rights of its members. The only success that had so far crowned their efforts was the grant of an official gown by the Council of the Colleges, but he hoped for even greater privileges in the future, especially that of granting the style of "member" instead of "licentiate" to the College of Surgeons' diplomates. Dr. Fitzgerald, ex-M.P. for Longford, replied in a witty speech, in which he compared the grievances of the Irish with those of the sister nation. Mr. Sidney Stephenson, in happy terms, proposed "The Visitors," and Dr. McManus, Dr. MacNaughton-Jones and Dr. Hubert Biss replied. Other toasts were "The President" and "The Officers of the Association," both spoken and replied to with enthusiasm. The gathering was graced by the presence of ladies, and was generally acknowledged to have been of an enjoyable and inspiriting character.

Cancer Research at the Middlesex Hospital.

Field-Marshal Lord Grenfell presided on May 28th at the Court of Governors of the Middlesex Hospital, when the weekly board reported that a Special Committee has been established, the members of which will devote themselves entirely to promoting the interests of the Cancer Charity, with a view to ultimately procuring its complete endowment, and ensuring that the important work of investigation carried out by the director of cancer research and his assistants shall in nowise be impeded by pecuniary considerations. In connection with the latter object an urgent appeal has recently been made in the public press for funds to meet the expenses of the current year, and of the £2,500 required for the purpose £1,000 has already been subscribed. Investigations into the difficult and complex problems of cancerous affections involve much labour, and, although it may be long before any decided practical results can be obtained, that labour is by no means fruitless. Every additional fact, however small, contributes to the better understanding of the conditions under which the diseases arise, the manner in which they spread, and the best methods of treatment to be employed. That in due time such knowledge will direct us where to look for the means of checking and preventing cancer there can be no doubt. Such a consummation will, however, only be attained by the exercise of unwearied patience and assiduity on the part of those engaged in the task, and it is essential that, possessing as they do the necessary scientific knowledge, they should have every facility given then to utilise it to the best possible advantage.

Professor Schafer's Method of Resuscitation from Drowning.

The Royal Life Saving Society has issued its annual report, announcing that 7,169 persons have qualified for its various awards as compared with 6,226 in 1906, making a total of 38,436 since the foundation of the society in 1892. The society in 1891 published an illustrated handbook explaining the methods for rescuing and resuscitating the drowning, etc., and so great has been the demand for it that a tenth edition has just been published. In this work most important alterations have been made, notably in the method of resuscitation. The society has adopted a system devised by Professor E. A. Schäfer, F.R.S., of Edinburgh University, which revolutionises the practice formerly deemed the best. The patient is laid face downwards, and natural breathing is encouraged by gentle and regular pressure on the lower ribs at the rate of about 15 times per minute. Among other new features in the book are a new method of rescue suitable for side-stroke swimming, and instruction on back swimming, over-arm, and the new crawl stroke, as also the conditions of examinations for the various awards of the society. Copies can be obtained, price 1s., from the chief secretary, 8 Bayley Street, Bedford Square, W.C.

Proceedings Against a Herbalist.

At Leeds on May 26th John Murgatroyd, a herbalist, aged 72 years, was charged with wilfully murdering Mrs. Kate Ellen Cavanagh, aged 30 years. The prosecuting solicitor said he did not anticipate being able to ask for a committal on that charge, but on one for procuring abortion by the use of instruments. The facts of the case, according to the solicitor, were that Mrs. Cavanagh visited Murgatroyd in the company of a Mrs. Fletcher. The man said he could give her some medicine. He also said he was not certain whether it would have any effect. Mrs. Cavanagh paid 2s. 6d. for the medicine. On August 8th last Mrs. Cavanagh and Mrs. Fletcher paid another visit to Murgatroyd.

There was no reference in the conversation between the woman and the man which would imply that an operation had previously been performed. Mrs. Cavanagh said her condition was unchanged, and finally an operation was agreed to. Immediately after the operation the woman collapsed.

A cab was sent for, and the woman was taken home. She never rallied, however, and made no statement. At four o'clock on the following morning she was seen by a medical man, a period of about five hours having elapsed between the operation and the woman being seen by a doctor.

Death took place on August 10th, a period of about 36 hours after the operation, and as a result of a post-mortem examination the doctor was compelled to come to the conclusion that some mechanical interference had taken place.

The conduct of Murgatroyd, remarked the solicitor, disclosed a callous indifference to the whole facts which was almost appalling. There would be, he continued, further proceedings against the man with regard to a case which had occurred at Burnley.

The man was remanded.

Formation of a Medical Benevolent Society for Yorkshire.

In the East and North Ridings of Yorkshire the need has long been felt of some Society which would have for its object the relief of aged members of the profession, or their widows and orphans. Though the question of the formation of such a Society has been raised on many occasions, it is only recently that any definite action has been taken. Some months ago a Provisional Committee was formed in Hull, which, after investigating the matter, decided that the formation of a Society on the lines of the West Riding Medical Charitable Society was most desirable, and the views of the whole of the medical practitioners (nearly 500 in number) in the East and North Ridings and the City of York were obtained by circular letter. The response was so satisfactory that a meeting was held at York on May 21st, and the Society was definitely formed. More than a hundred members have already joined, including a large number of life members. The annual subscription was fixed at one guinea, and for life members at ten guineas. Only members or their relatives can participate in the benefits. The first officers of the Society are:—President: Dr. J. Mitchell Wilson (Beverley); Vice-Presidents: Dr. Jalland (York), Dr. Godfrey (Scarborough), Mr. R. H. B. Nicholson (Hull), Dr. C. A. Lee (Hull), Dr. H. J. C. Godfrey (Bridlington); Treasurer: Dr. E. M. Hainworth (Hull); and Honorary Secretary, Dr. Edward Turton (Hull). From the support already received the future success of the Society would seem to be assured.

The Status of Prison Medical Officers in Ireland.

In reply to a question in the House of Commons last week by Mr. T. M. Healy, Mr. Cherry replied that, prior to 1877 the prison medical officers in Ireland were entitled to pensions under the Act then in force; but since the passing of the Prisons (Ireland) Act, 1877, only those medical officers who are members of the established Civil Service, and give their whole time to the service, are entitled to pensions. The only officers so entitled are two at Mountjoy Prison and one at Maryborough. Two of the existing medical officers of local prisons, who were appointed before 1877, are also entitled to pension. The remainder of the prison doctors are local medical men who have private practice. The fact that they are appointed for temporary terms of three years does not affect the question of pension. There is no ground for the assumption that these officers are not fully independent in the discharge of their duties. No case has yet occurred in which the temporary appointment has not been renewed at the expiration of three years. The change in the status of medical officers as regards pension was not made by any Government Department, but by statute.

The Elections at the Royal College of Surgeons, Ireland.

The election of the President, Council, and other officers of the College was held on Monday last, June 1st. The following were elected:—

President: *Mr. John Lentaigne, F.R.C.S.; Vice-President: *Mr. Robert H. Woods, F.R.C.S.; Secretary of the College: *Sir Charles A. Cameron. The following were elected members of Council (arranged in order of Fellowship seniority):—*Sir Henry R. Swanzy; *William Stoker, *Sir Charles A. Cameron, *Sir Lambert H. Ormsby, *Richard D. Purefoy, *Henry Gregg Sherlock, *Sir Charles B. Ball, *John B. Story, *D. Edgar Flinn, *Sir Thomas Myles, *Sir Arthur Chance, *Richard Lane Joynt, *R. Bolton McCausland, Thomas E. Gordon, *Edward Henry Taylor, G. Jameson Johnston, *William Taylor, *R. Charles B. Maunsell, *William Ireland Wheeler. (Those marked * have previously served as Councillors.)

Army and Navy Male Nurses' Co-operation.

The Hon. Secretary of the above Co-operation writes to draw attention to the fact that a misleading statement has appeared in print that it is not the intention of the Committee to deduct a sufficient percentage from the earnings of the nurses to cover the working expenses of the Co-operation. If this statement is allowed to go uncorrected, the public will conclude that the Committee will be continually appealing for funds, which is in itself a depressing thought. On the contrary, it is hoped that within a comparatively short time, and with a suitable deduction, sufficient nurses will be in employment to render the Society self-supporting. Already the demand for nurses is increasing every month. Funds are needed for equipping a residential home for the nurses and for advertising this most national enterprise.

Royal British Nurses' Association.

The annual meeting of the Royal British Nurses' Association will be held at 2.45 p.m. on Friday, June 5th, in the Council Chamber of the Caxton Hall, Westminster. H.R.H. the Princess Christian of Schleswig-Holstein will preside. Before the business meeting Her Royal Highness will present diplomas to the candidates who were successful in the Spring Examination of the Corporation. The reunion of members will take place at the Franco-British Exhibition, where tea will be served at 5 p.m.

Combined System of Medical Scholarships.

A combined examination for twenty-three medical entrance scholarships and exhibitions of an aggregate total value of about £1,500, tenable in the faculties of medical sciences of University College, King's College, and in the medical schools of King's College Hospital, St. George's Hospital, Westminster Hospital, and the London School of Medicine for Women, will be held in London by the London Inter-Collegiate Scholarships Board on September 22nd and following days. Candidates will be admitted to the examination for the scholarships and exhibitions under the various regulations governing them. Full particulars and entry forms may be obtained on application to the Secretary of the Board (Alfred E. G. Attoe, University College, Gower Street, London, W.C.), or to the deans (or secretaries) of the medical schools concerned.

NOTICES TO CORRESPONDENTS, &c.

☛ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

SUCCESSFUL ANÆSTHESIA.

A **coroner's** jury at Birkenhead recently came to a strange decision. A man underwent an operation and "died almost immediately from syncope, consequent on the action of chloroform." The jury then "returned a verdict in accordance with the medical evidence, and found that the anæsthetic was properly and successfully administered." If these words have any meaning, we can only conclude that the jury judged from the medical evidence that the doctors desired to kill their patient. At any rate, they are to be congratulated on their frankness.—*John Bull.*

Occupans.—The total number of cases of poisoning and of anthrax reported to the Home Office under the Factory and Workshops Act during April was 61, consisting of 53 cases of lead poisoning, 2 of arsenic poisoning, and 6 of anthrax. In addition to the above, 13 cases of lead poisoning (including 2 deaths) were reported during April among house painters and plumbers.

Arma Virumque.—It is rather a curious point to put to a medical editor! But, in order to justify the omniscience you impute to us, we may inform you that *any* motto may be used by any armigerous person. There is no grant of a motto, and consequently no heredity in it. If your opponent likes your motto and adopts it, you have no remedy beyond moral suasion.

OUT OF DATE AND UP TO DATE SURGERY—A CONTRAST.

The old time surgeons, dirty and unkempt,
Seldom from vermin or bacteria exempt,
Carried "death's warrant underneath their nails."
Men wondered why their operations failed;
But Lister came, and with him came the light,
Pasteur and Lister—names we must unite;
In common justice, *both* must share the praise,
They sought the goal, but both by different ways.
Now their results we all rejoice to see,
Aseptic! Cleanly! Modern Surgery!

London, W. A. D.

Mr. Hy. Watson.—Dr. Dakhyl, about whom you inquire, is a Turkish subject, having French degrees. The present position has arisen through his unsuccessful libel action against *Truth*, and his consequent liability for the costs, amounting to over £3,000.

F.R.C.S.I. will find full reference to the subject in our last issue. The report of the meeting of College on Saturday last, at which the question was discussed, will be found on reference to our "News" column in present number.

F. B. E.—Pressure on our space this week has precluded the insertion of your letter. It will be considered and inserted in our next, if deemed desirable.

Medical Officer.—We regret to state that the Society, which has done such excellent work, has gone to pieces. We understand that it may possibly be revived.

Meetings of the Societies, Lectures, &c.

Wednesday, June 3rd.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.)—4 p.m.: Mr. T. P. Legg: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. F. J. McCann: How to Diagnose Cancer of the Womb (with lantern slides).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2.30 p.m.: Medical Out-patient: Dr. Whipham. Skin: Dr. Meachen. Eye: Mr. Brooks.

Thursday, June 4th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture:—Mr. J. W. T. Walker: The Treatment of Stricture of the Urethra.

Friday, June 5th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Dr. H. Tilley: Clinique (Throat).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic:—Surgical Out-patient: Mr. J. H. Evans. 2.30 p.m.: Surgical Operations: Mr. Edmunds. Clinics: Medical Out-patient: Dr. Auld. Eye: Mr. Brooks. 3 p.m.: Medical In-patient: Dr. R. M. Leslie.

Appointments.

Davis, H. J., M.B.Cantab., M.R.C.P.Lond., Physician-in-Charge of the Throat and Ear Department at the West London Hospital.

English, Samuel, M.B., Ch.B.Glasg., Honorary Surgeon to the Pendleton Branch Dispensary of the Salford Royal Hospital.

Fothergill, W. E., M.D.Edin., Lecturer on Clinical Obstetrics and Gynæcology in the University of Manchester.

Hill, William, Surgeon-in-Charge of the new Department for Diseases of the Ear, Nose and Throat at St. Mary's Hospital.

Howarth, William James, M.D., D.P.H.Vict., County Medical Officer for Kent.

Kearney, J. J., M.B., B.S.Irel., Certifying Surgeon under the Factory and Workshop Act for the Rosscarbery District of the county of Cork.

Kelly, M. Fitzmaurice, M.B., B.S.Lond., F.R.C.S.Eng., Surgical Registrar at St Mary's Hospital.

Roberts, W. R. S., M.B., B.S.Birm., Certifying Surgeon under the Factory and Workshop Act for the Ongar District of the county of Essex.

Vacancies.

Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance, and washing. Applications to the Secretary.

Infirmary of the City of London Union.—Assistant Medical Superintendent. Salary £150 per annum, with furnished apartments at the Infirmary, rations and washing. Applications to Edward R. Woodward, Clerk to the Guardians, 61, Bartholomew Close.

Leicestershire and Rutland Asylum.—Junior Medical Officer. Salary £130 per annum, with board, lodging, and washing. Applications to W. J. Freer, Esq., 10, New Street, Leicester.

Burton-on-Trent Infirmary.—House Surgeon. Salary £120 per annum, together with furnished rooms, board, coal, and light free. Applications to the Hon. Secretary, Mr. John Wood, the Infirmary, Burton-on-Trent.

Lord Mayor Treloar Cripples' Home and College, Alton, Hants.—Resident Medical Officer. Salary £150 per annum. Aplications to Sir William Treloar, 122-3, Mansion House Chambers, E.C.

Carmarthenshire Infirmary.—Resident Medical Officer. Salary £100 per annum, with furnished apartments, board, attendance, fire, gas, and washing. Applications to Howell Howell, Secretary.

County Asylum, Burntwood, near Lichfield.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, attendance and washing. Applications to the Medical Superintendent.

Darenth Asylum.—Third Assistant Medical Officer. Salary £150 per annum, with rations, lodging, attendance, and washing. Applications to the Superintendent, Darenth Asylum, Dartford, Kent.

Norwich City Asylum, Hellesdon-next-Norwich.—Assistant Medical Officer. Salary £130 per annum, with rooms, board, laundry, and attendance. Applications to the Medical Superintendent.

Metropolitan Hospital.—Secretary. Salary £350 per annum. Applications to be sent to the Chairman, Metropolitan Hospital, Kingsland Road, N.E.

Births.

Barradell-Smith.—On May 24th, at 396, London Road, South Lowestoft, the wife of S. Barradell-Smith, M.B., B.C., of a son.

Bawtree.—On May 27th, at The Lodge, Maldon, Essex, the wife of Frank Bawtree, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

Hughes.—On May 20th, at 4, Kirtleton Avenue, Weymouth, the wife of Fleet-Surgeon Hughes, R.N., H.M. Dockyard, Malta, of a son.

Sowry.—On May 28th, at 4, King Street, Newcastle, Staffs, to Dr. and Mrs. Sowry—a son.

Soltau.—On May 30th, at 1, Lansdown Place, Plymouth, the wife of A. Bertram Soltau, M.D., F.R.C.S., of a son.

Wilson.—On May 22nd, at 185, Chevening Road, London, N.W., the wife of Thomas Wilson, F.R.C.S., of a son.

Deaths.

Richards.—On May 27th, at his residence, 150, Westhill, Putney, Samuel Atkinson Richards, L.R.C.P., M.R.C.S., L.S.A., etc., in his 76th year.

Ridge.—On May 25th, at Carlton House, Enfield, Middlesex, John James Ridge, M.D., B.A., B.S., B.Sc.Lond., Medical Officer of Health for Enfield, aged 61.

Peptogenic Milk Powder

Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 1/10 and 3/8 each.

'Pepsencia'

PEPSENCIA is an ever-ready digestive fluid possessing remarkable peptic and rennet activity. It contains pure pepsin, the vitality of which is unimpaired by chemical action or manipulation, and it is obtained by direct solution from the secreting glands of the gastric mucous membrane, every care being exercised to preserve its full physiological activity.

The usual dose is a teaspoonful before or after meals in all cases where pepsin is indicated.

Supplied to the Medical Profession in 4 oz. and 8 oz. bottles, at 1/10 and 3/3 each.

'Panopepton'

PANOPEPTON presents the entire substance of prime lean beef and best wheat flour in a perfectly soluble, diffusible, and absorbable form. It is at once a grateful stimulant and food.

For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6 oz. and 12 oz. bottles, at 2/2 and 3/8 each.

Specimens and literature will be forwarded on request.

FORMAMINT

An Excellent Antiseptic and Prophylactic in Diseases of the Throat and Mouth

EFFICIENT SUBSTITUTE FOR GARGLES

COMPOSITION: Vide Article on "Oral Sepsis" in *The Lancet*, Oct. 20th, 1906.

"A chemical combination of Formic Aldehyde and Lactose put up in the form of a compressed tablet."

"A non-toxic and trustworthy antiseptic in all ages, differing entirely from simple solutions of formic aldehyde in nature and in action being much more powerful, devoid of any irritating properties, and which on solution by the saliva sets free that disinfectant in a nascent form."

INDICATIONS: in all conditions of **SEPTIC SORE THROAT,** as **TONSILLITIS**—Simple, Septic and Follicular—**DIPHTHERIA, SCARLET FEVER, MEASLES, THRUSH,** etc.

"In ten cases of **Diphtheria** the treatment by Formamint Tablets was employed as a substitute for local treatment by disinfectant gargles, and in some of the milder cases anti-toxin was dispensed with. In all cases the improvement was rapid."—(*British Medical Journal*, January 13th, 1906, Epitome, page 8.)

"A proved antiseptic and bactericide, non-toxic in action, far more efficient than gargles or mouth washes, particularly suitable for children and entails no pain, and its portability is of considerable convenience."—*Medical Magazine*, March, 1907).

Samples & Literature on Application to

Annotations

‘Tabloid’ Liquorice Compound Powder

Compound Liquorice Powder is an agreeable and mild laxative specially suitable for women, children and weakly persons. The official product is, however, unsuitable for use in many cases because it contains no less than 50 per cent. of refined sugar. **This ingredient does not enter into the composition of ‘Tabloid’ Liquorice Compound Powder,** which possesses therefore an unique advantage for use when the administration of sugar is inadvisable. The superiority of the ‘Tabloid’ product is further enhanced by the high standard of its constituents, which are presented in an exceptionally pure and active condition.

‘Tabloid’ Liquorice Compound Powder is supplied to the Medical Profession, in bottles of 25 and 100, at *7d.* and 1/4 per bottle. Each product is equivalent to 30 gr. of the official powder, and represents Senna, gr. 5; Liquorice, gr. 5; Sublimed Sulphur, gr. 2½; etc.

⁂

‘Tabloid’ Mistura Alba

An efficient stomachic and carminative combination, which reinforces the normal gastric function. The ‘Tabloid’ product, containing exact amounts of pure active ingredients, enables a saline draught to be made with a minimum of trouble.

Each product contains Magnesium Sulphate, gr. 15; Magnesium Carbonate, gr. 2½; and Oil of Peppermint, min. 1/32. Supplied to the Medical Profession, in bottles of 100, at 1/8 per bottle.

⁂

‘Tabloid’ Astringent Mixture

A valuable preparation of astringent, aromatic, antispasmodic and anodyne power. With the ‘Tabloid’ product an efficient draught is readily prepared, containing the complete activity of each constituent.

‘Tabloid’ Astringent Mixture corresponds to the Board of Health formula. It is supplied to the Medical Profession, in bottles of 100, at 2/6 per bottle.

‘Tabloid’ Reduced Iron and Rhubarb Compound

Many preparations of iron are unpleasant and even nauseous; they derange digestion, they are astringent, and they are with difficulty absorbed. Reduced iron contains a large percentage of iron in a non-irritating and non-astringent form. It is well tolerated, is readily absorbed and quickly shows its effect. The addition of rhubarb increases the usefulness of the ‘Tabloid’ product. ‘Tabloid’ Reduced Iron and Rhubarb Compound causes no griping nor constipation, and is valuable for the purpose of increasing the amount of hæmoglobin and the number of hæmocytes. It makes healthy blood and a healthy circulation, to supply vital oxygen, promote proper metabolism and form healthy tissue. The ‘Tabloid’ product enables iron to be administered without the inconvenience and danger to the teeth which characterise liquid preparations.

Each ‘Tabloid’ product contains Reduced Iron, gr. 2; Extract of Hyoscyamus, gr. 1; Extract of Nux Vomica, gr. ¼; Compound Rhubarb Pill, gr. 1; and Oil of Caraway, min. ¼. ‘Tabloid’ Reduced Iron Compound is also issued, the formula being the same as ‘Tabloid’ Reduced Iron and Rhubarb Compound, except that the rhubarb is omitted. Either formula is supplied to the Medical Profession, in bottles of 25 and 100, at *7d.* and 1/6 per bottle.

⁂

‘Tabloid’ Aromatic Chalk Powder with Opium

This product corresponds to the official Pulv. Cretæ Aromaticus c̄ Opio. It presents the neutralising action of chalk combined with the valuable astringent, stimulating and soothing properties of aromatics and opium. The ‘Tabloid’ product provides a convenient means of administration in which the ingredients are of exceptional purity and activity.

Each contains approximately Chalk, gr. 1; Opium, gr. ⅛, with aromatics. Supplied to the Medical Profession, in bottles of 25 and 100, at *8d.* and 1/4 per bottle.

Allenburys Milk Food No1
For the first 3 months
Medical Testimony, Directions
Allen & Hanburys London
Allenburys Milk Food No2
Second food for infants
Allen & Hanburys London
"Allenburys" Feeder

The "Allenburys" Milk Food No. 1.
FROM BIRTH TO 3 MONTHS.
This closely approximates in composition to human milk. It keeps thoroughly well, is easily prepared, the addition of hot water only being necessary.

The "Allenburys" Milk Food No. 2.
FROM 3 TO 6 MONTHS.
Is similar to the Milk Food No. 1, with the addition of a small amount of soluble phosphates and albuminoids.

The "Allenburys" Malted Food No. 3.
FROM 6 MONTHS AND UPWARDS.
Is a partially digested farinaceous food, and requires the addition of boiled cow's milk and water.

A full descriptive pamphlet and samples will be sent on request.

NOTES AND COMMENTS.

Accommodation for Seamen.

THE Medical Officer of Health for the Port of London has spoken out in strong and fearless terms about the accommodation for seamen provided on merchant vessels, and it is quite time that the matter engaged the attention of the Board of Trade. The good persons who bewail the disappearance of the British sailor, and his replacement by Norwegians, Lascars, and other foreigners, have only to consider how low a standard of comfort and healthiness is reached by the conditions of life on a merchant ship, before realising that the seaman who prefers turning land-lubber to sailing on the deep is no bad judge. As the surroundings of the working-classes rise in complexity and healthiness the poor gain new ideas of decency and comfort, and it is not to be expected that men will give up their homes and go to sea if insanitary quarters are provided for them. Consequently foreigners, who have not British ideas of the necessaries of life, take to manning the merchant service in larger and larger numbers. Shipowners are fond of talking of patriotism when it suits their purpose, but it is an evil form of treason that makes them offer British seamen the alternative of living in pig-styes or being replaced by foreigners.

Abaft the Binnacle.

DR. WILLIAMS describes the accommodation provided for seamen as a "disgrace to the twentieth century," and he attributes this state of affairs to shipowners apportioning as little space as possible to the staff in order to have more space for cargo. It is recognised by many medical men that whereas a sailor's life should be the healthiest possible, especially as regards pulmonary tuberculosis, as a matter of fact, the cramped sleeping quarters and the want of ventilation when the men are below, more than outweigh the advantage of fresh sea air when they are on deck. Dr. Williams points out that one of the great difficulties in lighting and ventilating the men's quarters is that they are situated in the forecastle, where the amount of light is limited, and where in bad weather the ventilators have to be removed. The sea is the most conservative of institutions, and the chief reason why men are lodged in the forecastle is that they always have been from time immemorial, though there is no reason known to anyone why they should not be accommodated aft, where light and air in abundance can be easily provided. By the Merchant Shipping Act of 1906 great improvements were intended in the seaman's life, but if the administration of the Act is not better enforced than seems to be the case, it will not be of much benefit to anyone. Among the conditions found in forecastles by Dr. Williams were six square feet of floor space allowed per man; another where vermin abounded and the floor was covered with accumulated filth; and a third where no natural light penetrated to the men's quarters. It seems, therefore, that we have not yet exorcised methods of barbarism from the merchant service.

Open-air Schools.

THE Education Committee of the London County Council, it may be remembered, tried an interesting experiment last year, namely, that of establishing an open-air school at Bostal Heath. The report on this departure has just been issued, and we are not far wrong in characterising it as period-marking, if not epoch-making. The children selected for instruction were all weakly or anæmic, and the joint report of the medical officer and the executive officer shows that, as regards health, the results were little short of astonishing. Every single child was benefited, some more and some less, but in certain cases the result was remarkable, especially in the case of children suffering from active disease. Encouraged by their success, the Committee propose this summer to hold three open-air schools, at Forest Hill, Kentish Town, and Shooter's Hill respectively, each school to accommodate seventy-five children, under a head-teacher, three assistant teachers, a nurse, and a cook. The committee reckon that £2,000 will be needed for the establishments, but this sum is not to include food, and they are appealing for £400 or £500 to be subscribed privately for this purpose. It is not our business to suggest where the money should come from, but it is a simple fact that unless plenty of good food is forthcoming, fresh air in the greatest abundance will not restore children to health. At any rate, we heartily congratulate the Education Committee on their departure from tradition, and on the demonstration they have afforded of the possibilities of schooling under natural conditions in this country. We hope the experiment will soon become a practice.

Inquests and Operations.

MR. TROUTBECK is apparently anxious to be known as a reforming coroner, which is another way of saying that he likes to make specious departures from the methods of his fellows. Last week he held an inquest on the body of a woman who died in the Bolingbroke Hospital after an operation, performed by Sir Victor Horsley, for the relief of cerebral tumour. Sir Victor himself was called as a witness, and he took the opportunity to remark that the case presented no features of unusual interest, and he did not therefore understand why an inquest had been held. Mr. Troutbeck rejoined that operations were getting much more frequent, and that inquests on patients who died after them were imperative. In addressing the jury, he proceeded to say that if death were accelerated by an operation, the case was one for inquiry before the coroner, because the death was not a natural death. He believed the country was in a state of complete ignorance as to the proportion of deaths accelerated by surgical operations. "It was a serious matter, and one for which a legal remedy was undoubtedly required." In the Bolingbroke Hospital, he remarked 14 deaths after operations had occurred during the year, and with the delicate consideration which he shows when there is a chance of casting a slur on medical men, he remarked that one could not tell whether these deaths had been accelerated by the operations or not, "but a very serious condition of things stood revealed. He did not intend to let the matter rest." Mr. Troutbeck is out on the warpath, and with the support of his faithful henchman we can scent further trouble in the wind.

New Methods.

If it is proposed to hold inquests on all patients who die within measurable time after surgical operations, we shall be faced with a situation of grave possibilities. Presumably Dr. Freyberger will be called to decide if the operation accelerated death or whether the operation was justifiable, and it is hardly likely that surgeons will be content to accept the verdict of a coroner's jury founded on such evidence. In the first place, the calibre of the average coroner's jury is little calculated to cope with the immense difficulties of clinical medicine and the deductions drawn from clinical signs and symptoms; secondly, Mr. Troutbeck has not established a reputation for entering sympathetically into the difficulties of medical practice; and, thirdly, Dr. Freyberger is not accepted by English medical men as an authority on surgery. It would seem the merest of platitudes to say that only experienced surgeons are qualified to say in a given case whether an operation gives a patient a better chance of relief or of life than abstaining from an operation.

New Results.

But there are other and very serious dangers to the practice. If surgeons know that every death after operation is to be made the subject of debate and criticism in ill-natured halfpenny journals, there will be an inevitable tendency to consult their own reputations more than the patient's benefit, and they will abstain from those operations which the patient is quite willing to undergo, but which involve serious risk. The holding of inquests may make the number of deaths after operation fewer, but it will in a much greater degree increase the number of deaths which might have been averted by operation. Moreover, with the odium and publicity of an inquest staring them in the face, the relatives of patients will be unwilling to consent to surgical procedures in severe cases, and, again, the number of those who might have been saved will increase. It is necessary to look at this matter from the broadest standpoint.

LEADING ARTICLES.

THE ROYAL COLLEGE OF SURGEONS OF IRELAND AND THE UNIVERSITIES BILL.

Our readers have already been made aware of the danger which threatens the Irish College of Surgeons under the Irish Universities Bill, but we make no apology for returning to the subject. The annual meeting of the College last week showed to the world the unanimity which exists among Irish surgeons as to the need for the continued existence of the College and its School of Medicine. The spirit exhibited should be a sufficient answer to those cavillers who suggest that in the settlement of Irish education questions the College need not be considered. Among those who rallied to the support of the College of Surgeons were professors and teachers of other schools, who recognise how necessary to the profession is the threatened institution. The Royal College of Surgeons has been in existence for some hundred and thirty years, and though receiving small grants for a time, for the last hundred years it has received no public money whatever. Its income entirely depends on the receipts of the School, for at present it has no funds invested beyond some £7,000 accumulated in more prosperous times. That the School still holds its place in spite of the multiplication of medical schools is shown by the fact that last winter there were some hundred and forty students entered for classes in anatomy. There are five other medical schools in Ireland, of which four are substantially endowed. The Universities Bill now before Parliament proposes to establish a richly endowed school instead of the fifth, at present unendowed. Every one of these schools will be a university school, and will naturally train its students for university degrees. By reason of their endowments these schools will be able to offer education at very low fees, and will presumably be able to provide attractive bursaries and scholarships for poor but able students. The natural result will be that the School of the Royal College of Surgeons will be starved out, and as the College has no source of income but its School, it must go under also. In his speech at the annual meeting, the President-Elect, Mr. Lentaigne, now President of the College, cleared away some misunderstandings which may be present in the minds of those who do not understand the position of medical education in Ireland. It will be asked why the College needs a school, since the sister College in London has none. In the first place, the College will have no means of existence if its School disappears, and we do not think there is any need to labour the case for the persistence of the College. Again, there is no analogy between the conditions in Ireland and those in London. In Ireland schools of medicine are all attached to some examining and qualifying body, and none of them belong to hospitals. In London, as we know, the schools are attached primarily to hospitals, and are merely affiliated to, or recognised, by the qualifying bodies. In Ireland the question at present is of starving out the only non-university school by giving endowments to five university schools. As the College has clearly stated, it does not fear competition, but it claims that the handicap should be fair. The School has maintained its high position in open competition with its rivals, and it claims its right to continue in fair competition with them. We cannot do better than quote a few sentences from a letter addressed on behalf of the College to Mr. Birrell:—

"It may be asked why we have not obtained endowment from private sources, as our English sister College has done. But Ireland is a poor country, and in it benevolence flows along religious channels, while Government aid is most successfully sought for by organisations savouring of party. It is our pride that we have excluded from the purview of our College all matters other than 'the regulation of the profession of surgery,' and the maintenance of 'reliable and extensive system of surgical education.' We seek no monopoly of medical education. We do not desire to hinder or delay educational proposals wished for by any body of our countrymen. We only ask that, when such proposals are being carried into effect, provision will be made to prevent the destruction of an ancient and distinguished College, the closing of a large and increasing school, and, incidentally, the beggaring of such of its professors as rely solely upon the income of their Chairs for their livelihood. The most simple and effective safeguard would be an annual grant of an amount sufficient to permit us to maintain our College and its School in a state of efficiency. This sum we estimate at £5,000 per annum. Such an endowment would have the advantage of not disturbing whatever arrangements may have been entered into with regard to the new University, while it would leave us—an independent body—to fulfil our duties and to follow our traditions without interference."

The College, if it is to obtain its deserts, must have the unanimous support of the medical profession of the entire kingdom. We confidently claim for it that support.

MEDICAL LAW REFORM.

IN the speech of the President at the opening of the Session of the General Medical Council, a brief extract of which was contained in our report of the proceedings of that body, Principal MacAlister remarked that "the difficulty of obtaining remedial legislation, even for admitted evils, affecting the practice of medicine, was illustrated by the slow progress of the Medical Companies Bill in the House of Commons." This remark suggests, first, that the President, for a man in his position, is singularly lacking in acquaintance with methods necessary to set in motion legislative machinery; and, secondly, that he is still more ignorant of the quality and quantity of remedial legislation that is needed in any way effectually to remedy the defects of existing statutes. If the President will inquire, he will find that very few Bills of any class can nowadays be carried through by private members, and that in medical legislation the introduction of a measure by a medical member is almost alone enough to ensure its destruction; for then the powers of ignorance, prejudice, and fanaticism in both Houses are surely arrayed against it. The chances of the passing of the Bill now in the hands of Sir J. Batty Tuke are extremely remote, in spite of the respect in which he is held; but if the Bill did become law it would not inflict more than the most trivial of pin-pricks upon the huge monster, quackery, against which it is directed. Not more than one per cent. of quacks are practising under the cloak of the Companies Act, and if they were forbidden to do so they would be subject only to a very temporary and trivial inconvenience. There are more than a dozen other ways, besides practising as a company *not* "limited," in which they could with impunity palm themselves off on the public as fully qualified practitioners; and not one of them would need to give up his nefarious business in consequence of the proposed new law.

The case for drastic medical law reform is overwhelming. It is a pity that the General Medical Council do not recognise that fact, and take part in promotion of the movement by which alone the desired enlightenment of our legislators can be brought about—namely, through the medium of a Royal Commission. This fact has already been acknowledged, and is about to be acted upon by the British Medical Association.

A Royal Commission has been made more than ever necessary by the attitude of the newspaper Press. Hitherto it has been possible to name a certain number of leading papers which have refused admission to fraudulent advertisements, and on occasion have exposed and denounced medical quacks and quackery. The number of such papers is rapidly diminishing. Nearly the whole Press—like that of the United States and Australia—is now practically suborned by quackery; and it is, as a rule, impossible for an editor to attack this gigantic system of cruel and murderous fraud without stultifying himself in a fashion at once ludicrous and deplorable. We have before us a recent issue of one of the foremost papers of the day, containing an editorial article dealing with a system of quackery lately exposed in the Law Courts, and deploring the fact that advertisements, on the face of them misleading, should find admission to respectable papers. In the same issue of the same paper appears the advertisement of the quack alluded to. This advertisement had appeared previously for many months in an especially expensive column, and has since been printed in the same place on many occasions.

The Medico-Political Committee of the British Medical Association recommend that a report on illicit practice and the traffic in quack medicines and apparatus—the cloak for a great deal of fraudulent practice—should be prepared before application for a Royal Commission is made. In this the General Medical Council could easily take an important part, and we commend it to their consideration. Either of them alone, the Association or the Medical Council, have it within their power to draw up a report which would not only suffice to show the need for Government inquiry, but would be alone almost enough to compel the interference of Parliament. We base this opinion upon a study of the Report of the Australian Commissioners, with a copy of which we have been favoured by Mr. Beale. Mr. Beale was commissioned to inquire but had no power to call witnesses and examine them on oath, and nearly everything he has set down could be repeated with equal authority and more effect by the bodies we have designated. Mr. Beale, as a layman, unaware of the magnitude of the evils he was called upon to lay bare, was evidently filled gradually with amazement, horror, and indignation as the story unfolded itself, and his report is to some extent weakened by the constant expressions of his emotions. But, discount it as one may, it is an astonishing narrative of popular credulity on the one hand, and of cynical knavery on the other. Presentation of a similar report to our home Government would make the demand for a Royal Commission irresistible, and a Commission would make it plain that, whatever advantages to the profession might be given by adequate legislation, these advantages would be outweighed literally a thousand times by the benefits conferred upon the people and upon the classes—the poor, the ignorant, the weak—who have most claim upon the guardianship of the State. Instead of the paltry tinkering with the law to which the President of the Council referred, would it not be better for the

Medical Council to direct all its energies to the promotion of reforms which would promise to be at once sweeping, effectual, and permanent?

CURRENT TOPICS.

The Forthcoming Meeting of the British Association.

WE are glad to learn that the arrangements are well advanced for the meeting of the British Association which is to be held in Dublin at the beginning of next September. It is now some thirty years since the Association visited the Irish capital, though six years ago it held its meeting in Belfast. Naturally, great interest is being taken in the visit, and public bodies and private persons are vying in offers of hospitality to the Association and to its principal members. Trinity College, the Royal University, the Royal Colleges of Physicians and Surgeons, and the Royal College of Science, are opening their doors for the meetings of the various sections, and as these buildings are all within short distance of each other, the passage from one section to another will be easy. Of late years, of course, the scientific importance of the meeting has somewhat dwindled, and it is now rather a social gathering of people interested in science than a conference of men of science. The social side of the meeting, therefore, will be well looked after, and many social functions are in process of arrangement. Few cities are more pleasantly situated as regards surroundings than Dublin, and doubtless many excursions to places of interest will take place. Medical men who can fit the meeting into their summer holiday will enjoy the visit to Dublin under such conditions.

Dentists and Anæsthetics.

AT the meeting of the General Medical Council, the case adjourned from November of a medical man who had been charged with administering anæsthetics for unregistered dentists, was before the Council, and the Council, having gone fully into the matter, did not adjudge him guilty of "infamous conduct in a professional respect." As we read the case, however, this judgment was given in view of the gentleman's statement that he was unaware he was committing any offence, and no doubt seems to remain that if such a case should occur again, the Council might come to a different decision. In doing so, they would have the good sense of the profession behind them, for it would be quite wrong that unregistered dentists should obtain the assistance of qualified medical men in such a way as to mislead the public into regarding them as reputable practitioners. The medical profession is willing to assist the dental profession in the suppression of quackery, but something is owing in return. It is not merely in the interests of the medical profession, but of the public, that we maintain that it is improper for anyone but a qualified medical man to administer an anæsthetic. If dentists expect the support of medical men in the guarding of their professional privileges, they must be careful themselves not to trespass. The giving of anæsthetics by a dentist, who is not a medical man, or, still worse, by the dentist's mechanic, as commonly happens, is not only a gross infringement of the privileges of the medical profession, but a serious danger to the public. We trust that the British Dental Association, which has already done much to preserve the dignity of the dental profession, will draw the attention of its members to this consideration.

Enteric Fever in Belfast.

IT seems probable that at last the cause of the hitherto unexplained constant prevalence of enteric fever at Belfast has been discovered. The discovery is due mainly to the labours of Dr. Darra Mair, an inspector of the Local Government Board, and a member of the Commission appointed in 1907 to investigate the question. Exhaustive inquiry in every possible direction furnished no clue to the prime origin of the infection. The local water supply was completely absolved, and although one limited outbreak was traced to infected milk, and although it was evident that the general prevalence of the disease must from time to time have led to occasional or accidental sources of diffusion, the true source remained concealed. Dr. Darra Mair was, however, in the end able to demonstrate with sufficient clearness that the continued and exceptional prevalence of the disease was really due to the unrestricted gathering of cockles and other shell-fish from the sewage-laden shoals of the Lough, and the consumption of the molluscs generally uncooked—by the poorer classes of the people. It is now proposed to prohibit the gathering of the contaminated shell-fish for human food; but we do not notice any proposal to suitably reward Dr. Mair for the service he has rendered to the locality and to the State, in the carrying out of his laborious scientific investigation. Similar services to the public by any profession, except the medical, would not be allowed to pass without some recognition beyond the mere verbal thanks which the local authority may or may not be pleased to accord to Dr. Mair.

The New Peril.

THE introduction of electricity into daily life has been the means of creating a whole series of risks to the detriment of His Majesty's lieges. A fluid which flows with incredible facility and in unlimited quantity through solid metal, for the passage of which mere superficial contact establishes continuity, is obviously a force to be very carefully kept in hand, metaphorically speaking. Like the wind, we know not whence it comes nor whither it goes. A live wire comes into chance contact with a telephone wire, and incontinently the operator, hundreds of miles away it may be, is stricken even unto death. A broken trolley wire touches the tramway rail, and forthwith human beings and animals in the line of fire, irrespective of distance, writhe in their death agony on the ground, and he who seeks to succour them does so at his peril. The enemy awaits us at odd corners and springs upon us unawares. The pavement is strewn so freely with metal covers of various kinds of "boxes"—sewer, telephone, telegraph, coal-holes, and so on, that in a crowded thoroughfare the averages pedestrian impinges on about ten a minute. Any one of the metal covers may, at a given moment, be directly or indirectly in contact with a live something, and the unsuspecting passenger falls gasping to the ground, never to smile again. The superstitious "touch wood" to avert certain contingencies, but in future they will do well to concentrate their attention on the necessity of not touching iron. It has come to this that the careful man will shy at the sight of metal in the roadway lest by inadvertently treading upon it he may become post-mortem material. In this country the risk has been minimised by prohibiting the putting up of naked wires for the transmission of powerful currents of electricity, but the risk has in great measure only been transferred from the air, where it is out of the way, to the ground, where it may be impossible to elude, should it break loose. One simple precaution would be to insist that all box covers in the public way should be covered with an insulating material, and another would be the more general use of rubber soles to boots. A very reasonable suggestion is that all live rails should be painted in a bright colour, scarlet for choice, as a warning to trespassers. The next few years will witness an untold development of these dangerous conduits, suicide will be reft of its terrors, and in the event of a railway accident the travellers will be electrocuted long before they can be either saved or burnt alive. This may not be an unmixed disadvantage, but it is an alternative which we can hardly be expected to view with philosophical indifference.

A Tuberculosis Exhibit.

An interesting feature of the Irish village at Ballymaclinton is the Tuberculosis Exhibition on view in the Village Hall. This is a reproduction, on a small scale, of the Tuberculosis Exhibition now on tour in Ireland, and includes the following four sections, namely, Pathological, Veterinary, Appliance, and Statistical. The Pathological Section consists of specimens of human lungs and intestines in various stages of tubercular disease. The Veterinary Section comprises examples of tuberculosis in the lower animals, including diseased and healthy bones for contrast. The Appliance Section includes sputum flasks, tissue paper handkerchiefs, cheap spittoons from cardboard and peat, milk sterilisers, and appliances for the preparation of food for invalids and infants. This section is not yet complete, but when finished will include models of châlets and simple open-air shelters, with photographs of various Irish sanatoria. The Statistical Section consists of diagrams and maps showing the appalling death-rate from tuberculosis in Ireland. Copies of literature distributed through the medium of the Tuberculosis Exhibition in Ireland are displayed on a large reading-desk. This literature covers every aspect of tuberculosis: the causation, prevention and treatment, including, as it does, copies of lectures delivered by the Registrar-General of Ireland, Sir Robert Matheson, Prof. Osler, Prof. McWeeney, and Sir John Byers, together with simple directions as to ventilation, cleanliness, food and milk supply. The "contrast" bedrooms which were shown by the Exhibition on tour are reproduced here, and form a valuable object lesson. On the one side thorough ventilation, brightness, cleanliness and simplicity are portrayed; on the other, darkness, dust, heavy curtains, ragged carpet, tightly-closed window—in short, every accessory for the development and spreading of disease. Throughout the day brief lectures are delivered, and altogether the Exhibition is a striking example of ingenious enterprise.

PERSONAL.

Dr. Gerald Leighton, M.D., F.R.S.E., has been appointed Professor of Pathology and Bacteriology in the newly-constituted Chair of those subjects at the Royal Veterinary College, Edinburgh.

Miss Janet M. Campbell, M.D., has been appointed to the medical staff of the Board of Education.

Dr. D. Ferrier, F.R.S., will give the Bolingbroke Lecture of the South-West London Medical Society on Friday next at 9 p.m. His subject will be "Hysterical Paralysis."

Dr. Charles W. Chapman will preside at the annual dinner of the Southern Branch of the Durham University Medical Graduates' Association.

Sir Thomas Clifford Allbutt, K.C.B., F.R.S., will preside at the dinner of the Cambridge Medical Graduates' Club, to be held on June 20th at Downing College, Cambridge.

On the occason of a visit of the French Medical Association to London to visit the Franco-British Exhibition, Professor Landouzy will deliver an address to medical men in the Great Hall of St. Bartholomew's Hospital

Dr. James Kerr will deliver the Inaugural Lecture of a Whitsun course on School Hygiene organised by the Incorporated Society of Medical Officers of Health on June 9th.

Messrs. Pearce Gould and Harrison Cripps are offering themselves for re-election upon the Council of the Royal College of Surgeons of England at the expiry of their term of office, and amongst the new candidates are Messrs. Lynn Thomas, C.B., George Eastes, Arbuthnot Lane, C. B. Lockwood, and W. F. Haslam.

Mr. Grant Andrew has been elected President of the Glasgow Southern Medical Society.

His Excellency the Governor of Bombay has consented to preside at the Medical Congress to be held in that Presidency in February of next year.

Dr. A. F. Hertz, Assistant Physician at Guy's Hospital, has been appointed Lecturer in Materia Medica and Medical Pharmacology in the University of Oxford; and Dr. J. B. Leathes, Lecturer in Physiology in St. Thomas's Hospital, Examiner in that subject in the same University.

Dr. C. Powell White will give three lectures on Cancer under the Pilkington Cancer Research Foundation of the University of Manchester.

Mr. John Lentaigne has been elected President of the Royal College of Surgeons of Ireland for the ensuing year; Mr. Robert Woods, Vice-President; and Sir Charles Cameron, C.B., Secretary.

Sir William Church presided at the annual meeting of the Convalescent Homes Association on May 20th.

The Board of Governors of the Richmond, Whitworth, and Hardwicke Hospitals have appointed Dr. C. H. O'Rourke, house physician, and Dr. G. T. Shepherd house surgeon.

A Clinical Lecture

ON

SOME LANDMARKS IN THE STUDY OF TUBERCULOSIS. (a)

By WILLIAM ST. CLAIR SYMMERS, M.B., C.M.Aberd.,

Professor of Pathology, Queen's College, Belfast.

That tuberculosis is a contagious disease is the conviction of most modern physicians. Still, the whole subject is beset with so many difficulties, and is attended with so many conflicting views, that it may interest us to look into a few of the more important issues of the case.

At the beginning of the last century, many of the leading French clinicians denied the contagiousness of pulmonary phthisis—*e.g.*, Laennec, Andral, Chomel, Trousseau—all men of outstanding ability and of great clinical acumen and experience, taught that phthisis was not a contagious malady. Laennec (1) stated that the passage of tuberculous material from a diseased to a healthy man, with *phthisis* as a result, was improbable. He argued that, among the poor, a large family could live in a single room with a phthisical person among them—a husband could live with a phthisical wife, and still no transmission of the disease takes place. Again, he had known repeated examples of people using the unwashed mattresses and bed-clothes of those who had died of phthisis, and no untoward result followed.

Among his examples of the non-contagiousness of phthisis, he cites a certain sisterhood over which he had medical charge, and in which, during ten years, the whole household, with a few exceptions, was renewed two or three times owing to deaths from phthisis (2). In this case he attributes the phthisis, not to contagion, but to melancholy emotions—*passions tristes*—attendant on the extreme rigour of the life and constant thought of the more terrible aspects of religion. But in this same connection he states (3), as if in reserve of judgment, that "many facts go to prove that a disease which is not usually contagious may become so under certain circumstances." Laennec held the view that tuberculous matter once developing in a pre-disposed person—once forming "tubercules" in the body—was metastatically infectious, and so invaded the tissues of the individual, involving a greater or lesser area until the patient succumbed. But still, while denying the phthisis-producing power of tuberculous material, denying that phthisis is contagious, he gives (4) a masterly description of a tubercle forming contagion in his own personal experience. Having inoculated his left forefinger by a scratch when sawing a tuberculous vertebra, there developed a small yellowish nodule exactly resembling a "crude yellow tubercle." This accident happened to him in 1799, and after twenty-one years he showed signs of phthisis incipiens. He died of phthisis six years later. There are not wanting authorities (*e.g.*, v. Behring) (5) who believe that the finger wound was in all probability the original infection of the phthisis of which Laennec died twenty-seven years after. By the side of this view, be it mentioned that Laennec's mother died of phthisis when he, afterwards so justly renowned, was a child of six years of age.

Nineteen years after Laennec's death, J. A. Villemin (6), latterly of the Val de Grace Hospital in Paris, published (1865-1869) a series of memorable experiments in which he demonstrated once for all that the products of tuberculous lesions were capable of conferring tuberculosis when inoculated into animals. In these experiments he used principally rabbits, and he showed that these and other animals could be infected with tuberculous matter—that is, that if tuberculous matter from phthisical cavities, or caseous matter from various human organs were introduced into the body of the rabbit (by placing such matter subcutaneously at the root of the ear), these animals became tuberculous. Further, he found that tuberculous matter from the cow was also capable of producing tuberculosis in the rabbit, and he states that this infective material from bovines was effective in communicating a much more rapid and more generalised tuberculosis than was obtainable with the matter from human sources (7). Thus he was acquainted with a fact which has been insisted upon in recent years—viz., that bovine tubercle produces in rabbits a more rapid and more extensive infection than is obtainable when human tubercle is inoculated into these animals. Goats and guinea-pigs were also proved to be inoculable, but dogs were more resistant, and sometimes remained unaffected—they never died, but tubercles were found if the animal were killed. Three cats were subcutaneously inoculated, and two of them showed slight signs of tuberculosis. As to birds, it was found that repeated inoculations of a cock and a ringdove led to no trace of tubercle. This is in accordance with the modern view that fowls do not contract tuberculosis from swallowing human tuberculous sputum. Further, he found that sputum from phthisical patients was infective to rabbits when subcutaneously injected. One of the rabbits thus tuberculised was found to show no lesions in the lungs. This fact, says M. Villemin, was the first example (8) that he obtained of an exception to what was known as the "Law of Louis," this law formulating that the lungs are particularly prone to tuberculosis, that they are always the first and occasionally the only organs to become affected. In continuation of these epoch-making experiments, Villemin investigated the infectivity of caseous pneumonia and of scrofulous glands, of the blood of tuberculous men and rabbits; also the effect of intra-tracheal injections; and among other positive results he showed that tuberculous matter is continuously infective when passed from rabbit to rabbit through a series of these rodents. As to the blood, he succeeded in producing tubercle by subcutaneously injecting 2 c.c. of defibrinated blood from the rabbits' femoral artery. Again, 2 c.c. of blood from the liver of a man who had died of phthisis produced, in a rabbit, tuberculosis of marked intensity and extent, with a fatal termination in six weeks' time. But, with blood obtained by "cupping" from living patients, the results were less striking. Three of the four rabbits used remained unaffected. The fourth showed a local caseous mass the size of a "small nut" at the point of inoculation, and a few grey tubercles in the lungs.

In marked contra-distinction to the positive results obtained by inoculation of tuberculous matter was his uniform and invariable failure to produce tuberculous lesions when he injected non-tuberculous products—*e.g.*, pus from various sources, "cancerous" material, pneumonic products, the exudate from a pleurisy complicating typhoid fever, and also, in answer to certain criticisms, he showed the non-tuberculous nature of the so-called "verminous tuberculosis" (9) of sheep. Moreover, he pointed out to his critics that spontaneous tuberculosis of the rabbit is an extremely rare condition, and he insisted that the well-known tuberculiform disease of rabbits was anything but a genuine tuberculous condition, but was due to certain peculiar "oviform bodies" now known to be of protozoal nature—coccidia (10).

(a) Lecture delivered to the Students of the Royal Victoria Hospital, Belfast, February 22nd, 1908.

Villemin's famous demonstrations were speedily tested, and verified by various observers (Klebs, Cohnheim, Salomonsen), and then, under the influence of Pasteur's work, men began to look for a *living* germ. Baumgarten (11) was the first to see a bacillus, by treating sections of tuberculous organs with diluted caustic potash, which was doubtless the responsible organism. But, as all the world knows, it was reserved for Robert Koch (12) to place the matter beyond all dispute by his immortal discovery of the specific bacillus in 1882, by its isolation, its cultivation, and by the proof that all the protean manifestations of tuberculosis are due to the parasitism of a definite vegetable micro-organism in the animal body. At least, so it seemed for several years after Koch's great achievement. At first tubercle bacilli were regarded as being of one kind, or species, as being identical, no matter from what animal they were obtained. Thus the bacilli from human, bovine and avian sources were considered to be one and the same thing—to be identical. Then certain doubts arose.

Professor Koch (13) was the first to demonstrate acid-fast bacilli in the lesions of the so-called tuberculosis of fowls, and he saw what has since been repeatedly observed—viz., that these bacilli are present in much greater numbers than in mammalian tuberculous products. Koch did not at that time cultivate the bacillus from the fowl, and, moreover, he was only partially successful in inoculating fowls and pigeons with pure cultures of mammalian tubercle bacilli. Soon other observers began to find great difficulty, or, indeed, met with total failure, in transmitting mammalian tubercle to fowls—*e.g.*, Strauss and Wurtz (1883) (14) fed a number of hens for six months to a year with tuberculous sputum and with pieces of tuberculous human lungs, and to such an extent that each hen swallowed in all 4 kilogrammes of sputum, and yet there was no emaciation and no trace of disease! But still, cases were reported of hens becoming affected when they swallowed tuberculous sputum—*e.g.*, by Johne and by Bollinger. A very curious thing was reported by Martin (15). He inoculated hens and pigeons intra-peritoneally with mammalian tubercle. These animals remained in perfect health, but when killed some months after the inoculations, it was found that their blood, on injection into guinea-pigs, was infective, and tuberculosis developed as the result. Rivolta (16) had a somewhat similar experience. He inoculated hens with tuberculous material. After 34 and 54 days the hens were sound, but the inoculated material still contained tubercle bacilli, and when removed from the hen to guinea-pigs, rendered the latter tuberculous. Again, it was found that avian tubercle bacilli did not produce in guinea-pigs and rabbits the characteristic lesions that are so easily produced in these animals when mammalian bacilli are injected. Both avian and mammalian tubercle bacilli kill these rodents, but the avian bacillus does not produce the macroscopic tubercles, or at least such tubercles, both in the guinea-pig and the rabbit, are very exceptionally produced by the avian, but are the rule in infection with the mammalian bacillus.

In short, as far back as 1883, the Italian worker Rivolta concluded from his experiments that a distinction must be drawn between tubercle bacilli of avian and mammalian sources. Rivolta argued from the difference shown by these micro-organisms in their action on the experimental animals, the bacilli are admittedly alike in certain important respects, but they do not coincide in pathogenic action on rabbits and guinea-pigs. Rivolta goes so far as to declare that "fowl tuberculosis is called forth by an infection which specifically differs from human and bovine tuberculosis."

Rivolta's views, as just stated, were based on animal experimentation. These views were soon to be strengthened by the work of Angelo Maffucci (17), Professor of Pathological Anatomy in the University of Pisa. Rivolta had received a culture of the avian bacillus from the famous French veterinarian Nocard, Nocard being the first to obtain such cultures, which he succeeded in isolating from a pheasant. Rivolta gave cultures from this to Maffucci, and the Pisan savant (1888) showed that there are marked differences between the avian and mammalian bacillus to their cultural features, and Prof. Koch (Tenth International Congress, Berlin) agreed with Maffucci. Moreover, Maffucci, working with cultures isolated from hens, as well as with Nocard's original strain from the pheasant, was able to adduce a number of important verifications of previous work, and also to bring forward new facts pointing to a distinct dissimilarity between avian and mammalian tubercle bacilli. For example, these cultures were tested on hens in various ways by intra-peritoneal, intramuscular, intra-venous and intra-tracheal injection, the result proving that the bacillus infected the hens with tuberculosis, and was therefore the cause of the disease. The liver and spleen are the organs most extensively affected, whereas the lungs are much less liable to the tuberculous changes. Maffucci's endeavour to infect hens by *feeding* them with pure cultures and with the liver of a diseased fowl (swarming with myriads of bacilli) resulted in a complete negative. This failure is in accordance with the previous attempt of Ribbert to infect fowls by feeding them with the dejecta of tuberculous hens. Ducks succumbed to intra-peritoneal injections. The rabbit was more resistant. One out of two showed some scattered caseous nodules in the lungs four months after peritoneal injection, whereas subcutaneous inoculation, although leading to emaciation and death, was unproductive of any positive tuberculous lesions. Dogs were still more resistant than the rabbit. Guinea-pigs could be killed by injections of the bacillus, but even when the bacilli were introduced in large quantities directly into the circulation, there was no formation of tubercles in the organs.

An important fact determined by Maffucci (18) is that it is impossible to infect a series of guinea-pigs by transmission from animal to animal. The bacillus disappears completely after the second passage. Maffucci concluded from this fact that he was not dealing merely with a weakened tubercle virus, seeing that the bacillus, instead of acquiring increased virulence by passage through an animal eminently susceptible to mammalian tubercle, actually was destroyed in the body of such an animal even after two passages. Since avian tubercle bacilli do not communicate a genuine tuberculosis to the usual research animals, how do mammalian bacilli affect fowls? This question has been answered in no uncertain voice by many investigators, as already mentioned. In Maffucci's hands the result was a practical negative: 22 hens were variously treated with tubercle bacilli of human or bovine origin—*e.g.*, 2 were injected with tuberculous sputum—result, no lesions; 3 were intra-venously injected with bacilli—result, 2 died greatly emaciated after two months, but there were no tubercles to be seen; the third was also free from every trace of tuberculiform eruption. In fact, 1 hen alone showed anything like a tuberculous infection; this hen had been injected (intra-muscular?) with bovine tubercle bacilli (or tuberculous material?), and died 35 days afterwards. There were a number of hard, grey nodules on the intestinal serosa, and nothing else. These nodules microscopically discovered no bacilli; neither could cultures be obtained from them; but they produced tuberculosis in guinea-pigs. It is very interesting to note that these tuberculous nodules, when further inoculated into a second hen, were fatal, but from the liver no cultures were obtained, neither were there histologically any traces of tubercle in any of the organs. Thus it appears that the fowl reacts to mammalian tubercle as the guinea-pig does to avian tubercle. Each may succumb to an intoxication or partial infection, but in each case the animals show a high degree of insusceptibility and a complete racial immunity. To repeat: the fowl rejects mammalian tubercle, the mammal refuses avian infection. But here it must be mentioned that the parrot (19) occupies a peculiar position in its susceptibility to tuberculosis. It can acquire avian tuberculosis, but it is more susceptible to the human bacillus, and still more so to the bacillus of bovine tuberculosis. And again: Lydia Rabinowitch (20) has found bacilli of the mammalian type in two

African eagles, and in some other birds of prey in the Berlin Zoological Gardens.

Thus it would be going too far to say that birds *never* suffer from mammalian tuberculosis; but it would seemingly be a still greater error to assume that the ordinary "tuberculosis" of birds is in causal agency, absolutely identical with that of the mammalian disease. Also bacilli of avian imprint are said to have been found in men and other mammals, and, if this be true, we must be prepared to recognise pathological conditions due to this form of infection (21).

The duality of avian and mammalian tubercle bacilli, however interesting in itself, sinks to a secondary place when compared to the next phase of the question—viz., Is mammalian tubercle a unity? Are human and bovine tubercle bacilli identical organisms? As pointed out by Dr. P. W. Lathom (22), in the *Lancet*, Virchow, two years before Koch announced the discovery of the tubercle bacillus, laid great stress on the anatomical characters that distinguish human from bovine tuberculosis (perlsucht). In reference to Kleb's success in producing "pearl nodules" in a calf by injecting human tuberculous matter, Virchow recalls the fact that other substances also may cause tubercle-like formations, and he postponed his decision until the presumed bacillus should be discovered. In the meantime he pointed out that perlsucht runs a different course from human tuberculosis, that firmer nodules are formed, and that there is less tendency to caseation and ulceration. Phthisical ulceration of the lung does not occur in cattle. Koch himself states that from the first he was reserved in identifying human and bovine tubercle bacilli, having no sure proof either of their identity or their distinctions. Among those that latterly began to doubt the identity of the two bacilli, we may particularly mention the American bacteriologist, Theobald Smith (23), who in 1898, published certain results which point to differences between tubercle bacilli from human and bovine sources respectively. Bovine bacilli (and also those from cats, horses, pigs) grow on culture media less luxuriantly than do tubercle bacilli of human origin. Bovine bacilli are short, thick, plump, unequally staining rods, whereas human bacilli are delicate, slender rods, often somewhat curved, and stain equally throughout. Again, the two bacilli act differently on the glycerine in the culture media (24), the bovine causing a lasting diminution of acidity, but the human, after a preliminary diminution, causes a persistive increase of acidity. In other words, the bovine bacillus is an alkali-former, whereas the human bacillus begins as an alkali-former but ends as an acid-producer. Theobald Smith also found that the bovine bacillus is much more virulent to the rabbit than is the human bacillus. Thus he, working with cultures, verified what Villemin many years before had found while working with the tuberculous products of the then unknown bacillus. Smith, therefore, distinguished a "human" or "sputum" and a "bovine variety" of the tubercle bacillus. The question was soon to become of world-wide notoriety, not only among scientific workers, but owing to its economic implications it was also to occupy the attention of most of the greater Governments. This extended interest dates from a lecture delivered by Koch (25) in London, July 23rd, 1901, before the British Congress of Tuberculosis. On that day the distinguished German scientist announced his conclusions, with sufficiently sensational effect:—"I feel," said he, "justified in maintaining that human tuberculosis differs from bovine, and cannot be transmitted to cattle." And in discussing the converse problem—viz., man's susceptibility to bovine tubercle, he said:—"I should estimate the extent of infection by the milk and flesh of tuberculous cattle, and the butter made of their milk, as hardly greater than that of hereditary transmission, and I therefore do not deem it advisable to take any measures against it." As regards hereditary transmission, he had stated at the beginning of his address that it does occur, but is extremely rare, and "may be left absolutely out of account." In support of his main contention—viz., the non-transmissibility of human tubercle to cattle—Professor Koch detailed certain cattle experiments which, during the two previous years, he had carried out in conjunction with Professor Schutz, of the Berlin Veterinary School. The gist of these experiments is as follows:—Nineteen animals were tested with tuberculin, and, being found free from tuberculosis, were subjected in various ways to tubercle bacilli of human origin. Sputum or bacilli were injected subcutaneously, intra-venously, or intraperitoneally; moreover, some of the calves were fed almost daily for seven to eight months with tuberculous sputum. After eight months the animals were killed. None of them were tuberculous, although some showed small suppurative foci containing tubercle bacilli, exactly what happens when dead tubercle bacilli are injected under the skin of susceptible animals. "So the animals we experimented on were affected by the living bacilli of human tuberculosis exactly as they would have been by dead ones—they were absolutely insusceptible to them." But when, as a control, cattle were inoculated with tubercle bacilli of bovine origin, they showed, after about a week's incubation, signs of disease, fever, weakness, emaciation, and died in from six weeks to two months. Post-mortem their bodies showed extensive tuberculous disease. "In short, the cattle proved just as susceptible to infection by the bacillus of bovine tuberculosis as they had proved insusceptible to infection by the bacillus of human tuberculosis." Feeding experiments showed an equal distinction between the two bacilli. Such, then, was the trend of Koch's remarkable address. The result has been that an extensive amount of research work has been directed toward this question. Commissions have been appointed by Germany, England, Russia, Sweden, and the United States of America to inquire into the subject, and numerous independent workers have busied themselves in this great controversy, which, indeed, is still a matter of the keenest difference of opinion. Among British investigators it is generally held that Koch's views are utterly mistaken. For example, there is one argument advanced by Koch which is certainly assailable, resting, as it does, upon a pure assumption—viz., Koch argues against the intestinal origin of abdominal tuberculosis in children on the ground that primary disease of the bowel is rare. This, of course, assumes that the intact intestinal wall is impervious to the tubercle bacillus, and that a lesion of the bowel, a primary lesion, is necessary if the bacillus is to infect the body by this channel (26). He states that if infection occurs by alimenta, there should be primary intestinal tuberculosis. He himself has only twice seen such a thing, and he quotes Biedert as having observed the condition in only 16 out of 3,104 autopsies. The answer is simple: tubercle bacilli do pass through the wall of the intact gut, and, in so doing, leave not a trace behind. This fact has been established by various observers by direct experiment, and has been taught for years—*e.g.*, I have a vivid recollection of hearing this fact emphasised by Professor Hamilton, of Aberdeen, more than twenty years ago—the fact, namely, that abdominal tuberculosis in children is seldom accompanied by a tubercular lesion of the intestinal mucosa, and the suggestion that the frequency of mesenteric tubercle in children, with disease of the intestinal mucosa, points to the strong possibility that the bacillus passes through the intestine to the glands without causing a lesion of the former. The truth in this suggestion met with its first experimental verification at the hands of Sidney Martin (27), who, in 1895, proved, by feeding 4 pigs with bovine tuberculous matter, that the mesenteric glands became tuberculous, while there was no sign whatever of a mucosal lesion of the bowel. Moreover, the recent beautiful experiments of Calmette and Guérin (28), and of Vansteenberghe and Grysez (29), convince us more elaborately of the same infective peculiarity. Nor, indeed, is this traceless transpassage of the bacillus to be much wondered at, seeing that the larvæ of anchylostomum duodenale—objects greatly larger than bacteria—are able to penetrate the unbroken skin, leaving no trail behind them (30). The analogy, although forced, is not uninstructive.

As an example of the tenour of recent work in answer to Professor Koch's experiments, we may cite certain results obtained by Hamilton and McLauchlan Young (31), in an investigation into the relationship of human tuberculosis to that of bovines. Broadly speaking, the Aberdeen investigators obtained results that were in direct contradiction to those alleged to have been obtained by Koch and Schutz. I need not detail these experiments. They were numerous, they were surrounded by elaborate precautions, they were guided by the greatest English-speaking pathologist of the day—D. J. Hamilton—and they were in open contradiction to the statement that cattle are insusceptible to human tubercle. "Human tubercle is probably not so virulent for the calf as that derived from bovines, yet can be readily inoculated upon that animal." "When human tubercle has been engrafted upon a calf, it gains enormously in virulence by being re-inoculated upon a second calf." "When administered by the mouth, tubercular sputum induces an abdominal lymph-gland tuberculosis without necessarily the intestine being in any way involved." Such are some of the conclusions reached by Hamilton and Young. Further, these workers favour the view that the human bacillus and that of bovines are identical, but modified somewhat by their environment. The morphological characters of the bacillus may vary, but are no sure guide as to its source. But still the question is open to new elucidations, is not yet beyond the doubts of controversialists. Dr. Weber (32), of the Imperial Health Department of Berlin, implies an objection to at least one of Hamilton and Young's experiments. He thinks that the spraying of tuberculous sputum in large quantities into the nostrils of a calf may have owed its successful infection to the enormous quantities used. He finds that here is a bovine type and a human type of the bacillus; that the human type is not progressively pathogenetic for cattle; that men may at times harbour the bovine bacillus, and such men furnish a bacillus which, naturally, is infective for cattle.

When we pass away from the question as to the susceptibility of cattle to human tubercle bacilli, and approach its converse—viz., are men infectible with bovine tubercle bacilli?—we, of course, encounter a subject that cannot be put to the arbitrament of direct experiment. And, unfortunately, some reputed cases of infection with bovine bacilli—*e.g.*, by tuberculous milk—have been so uncritically reported, and have so completely broken down on careful examination, that, instead of teaching a valuable scientific lesson, they have had only the more modest merit of suggesting considerable scepticism in adopting information. A bad argument is worse than no argument. The most monumental of these anecdotes is, perhaps, the one furnished by Auguste Ollivier (33), in reference to tuberculosis in a ladies' school at Chartres. It appears that 13 girls died of tuberculosis within a space of two years, and that the milk had been taken from a tuberculous cow with a tuberculous mammitis. This was claimed as an example—*une démonstration catégorique*—of the transmission of tuberculosis by milk. But later on M. Ollivier gave some further details. The first girl to die of tubercle had succumbed before the cow was bought, and the remaining twelve never received a drop of this cow's milk, it having been served exclusively to the teaching staff and servants, none of whom contracted the disease. This grim farce is not without its merits—it is a pleasing thing to note that M. Ollivier did not hesitate to do all that he could to redeem his first communication by a prompt relation of more accurately ascertained facts.

In conclusion of this brief introduction to a great subject, I should like to refer to the work of Vansteenberghe and Grysez (34) in reference to the passage of ingested matter from the intestines to the lung. Certain of their experiments have been repeated recently by Sir William Whitla and myself, and it appears that their statements are statements of facts. These fascinating investigations bear upon the fate of carbon particles introduced into the stomach of the research animals, and it is practically—nay, even absolutely certain that such particles pass through the intestinal portals *viâ* the lymph channels to the lungs. This occurs in the case of the adult guinea-pig with little or no hindrance from the mesenteric glands, whereas with immature (baby) guinea-pigs the mesenteric glands act as a sieve and retain the offending bacilli or carbon particles, with the result that a "tabes mesenterica" occurs. Whitla and myself found tubercle bacilli in the lungs four hours after introducing tubercle bacilli into the stomach of an adult guinea-pig. Take a concrete example: Whitla and myself, repeating the experiments of Vansteenberghe and Grysez, introduced, through an œsophageal tube, a thick emulsion of Indian-ink into the stomach of a fully-grown guinea-pig. This we repeated daily for four days; then the animal was sacrificed, and we found the intestines and the mesenteric glands completely sound, whereas the lungs were veritably crammed, nigrified, with collections of jet-black carbon accumulations forming a pulmonary picture of anthracosis that was striking in the extreme. Tubercle bacilli, when swallowed, or when artificially placed in the stomach, are "absorbed" by the intestinal lymphatics, and are carried with surprising rapidity to the lungs. Prophecy is seldom apt, but I venture to believe that within a few years there will not be an instructed pathologist whose creed will exclude the entire acceptance of the doctrine of an intestinal origin for tuberculosis of the lungs. A modified view of the ingestional origin of pulmonary tuberculosis is that so strongly upheld by v. Behring (35), who believes that the disease results from an intestinal infection, but that almost invariably this infection dates from an early age, remains latent, it may be for many years, and then in adult life the victim succumbs to an infection contracted in infancy. This view was announced by v. Behring in February, 1903, at Cassel.

ORIGINAL PAPERS.

A NEW GENERALISATION IN SERUM THERAPY. (*a*)

By D. MONTGOMERIE PATON, L.R C.S. AND P. EDIN.

EHRLICH'S theory of the formation of antitoxins by cast-off cell receptors, and its seeming confirmation by the success of diphtheria antiserum, have been potent factors in establishing present opinion on the subject, and yet no two things have contributed so much to hinder the real progress of this method of treatment.

Ehrlich's theory conceives of cell receptors cast off by an increased cell reaction and floating in the blood. Hence the possibilities of treatment under such a theory are limited to the neutralisation of toxin, while it is still unattached, and has not attacked the tissue cell. True, by it the cell can still react for itself, but, so far as the theory goes, it is practically beyond the reach of any further assistance from the anti-serum which is being used.

The theory takes no notice of the elements in the serum which have caused the reaction in the cell which produced the excess of cell receptors, nor of whether they can also be transferred to the patient to produce the same cell reaction in him as in the animal producing them. These elements are in all serums, and yet they are unaccounted for.

The theory includes all the defence under the one method of resistance. It does not differentiate between the product of a tissue cell, which can only reproduce itself or its parts, no matter what the nature of the attack is, and a gland or system of glands like the lymphatic which is capable of elaborating a definite chemical secretion, the nature of which is determined by the character of the stimulus applied to it. And this capacity such glands have within fairly wide limits, while it is entirely absent from other tissues. The consequence is that, while this does not matter much in the animal itself, it has a profound effect on the hypodermic injection of the serum in determining what elements, and how much of them, can be successfully transferred to the patient.

Ehrlich's theory limited itself to antitoxins and bacteriolysins, but the advent of opsonins has shown that there are other resistances which are quite beyond the limits of the theory, and for whose existence the theory does not account. The same theory also explained the presence of the antitoxins and bacteriolysins as the response to a bacterial invasion, while opsonins are found under physiological and normal healthy conditions.

Many other objections could be raised, but it is quite evident that Ehrlich's theory, while it may be true in part, cannot by any means account for the whole resistance to microbic invasion, and it may be further stated that it does not by any means explain the actual results which have been already obtained.

The results of the oral use of serum which the writer has been obtaining for the last ten years have been the main factors, first, in creating discontent with accepted ideas, and, second, in bringing forward what to him seems a solution of the problem in which the work of all may be harmonised, and the way made clear for further advance.

The net results of investigation into serum therapy may be summarised as follows:—

(1) Antitoxic Serums.—Specific for the infection, and successful if given in time (diphtheria and tetanus).

(2) Bacteriolytic Serum.—Specific for each organism *in vitro;* of some value, but unreliable at any stage of the infection (streptococcus and plague).

(3) Serums derived from animals rendered immune, but which serums are of no value at any stage of the infection (typhoid and pneumococcus).

In each case the animal has been rendered immune, but the hypodermic exhibition of their serums divides them into three classes, according to its success or otherwise in transferring the immunity of the animal to the patient. Is there any rational explanation of such a differentiation in therapeutic value? A very extraordinary parallel is found to exist between the varying therapeutic value of those serums and the lymphatic resistance to the organisms used in their production:—

(1) The lymphatics are the first line of defence, and resist the entrance of toxin and organism.

(2) This resistance is vital in character; a specific glandular secretion, chemical in nature, and is not merely that of a filter, as it allows larger non-pathogenic organisms to pass freely.

(3) Therefore, lymphatic antitoxin must antagonise toxin and lymphatic bacteriolysin the organism.

(4) The quantity of this antitoxin and bacteriolysin in the serum will vary with the efficiency of the lymphatic resistance.

(5) The therapeutic value (the efficiency) of the serum depends on the quantity of antitoxin and bacteriolysin in it, and therefore depends on the lymphatic resistance.

Take the three varieties of serum, and their therapeutic value will be found to be exactly in proportion to the lymphatic resistance to the organism used in their production.

(1) Antitoxic Serums.—The organisms of diphtheria and tetanus are effectually excluded except in later stages of the disease.

(2) Bacteriolytic Serums.—The streptococcus and plague bacillus are very vigorously resisted, but the resistance is unreliable in its efficiency.

(3) Other Immune Serums.—The lymphatic resistance to typhoid and pneumococcus is in exact proportion to the therapeutic value of their antiserum, and that is of no practical value.

Professor Sir A. E. Wright, of late years, has made us familiar with opsonins, and it is clear that these substances are in all serums whether they be normal or the product of acquired immunity. Ehrlich's theory contemplates the production of surplus cell receptors only in response to pathological stimuli. When the cell and its surroundings are considered, it is clear that there must also be stimuli of a physiological character, which will produce a surplus of the same receptors. The cell has its normal function to perform, during which its vitality is often severely trenched upon, and the necessary stimulus is required just the same as though the cause had been a pathological one. Then it has to feed itself, and receptors have to be maintained for its food, and also for the taking up of the materials which go to maintain its integrity and function. The cell is in a continual condition of flux and reflux, and there is every reason for the presence of a surplus of cell receptors constantly present. A very small contribution by each cell would produce a considerable quantity of surplus receptors, and there would then be a physiological surplus which would act as an antitoxin to any toxin introduced whose haptophores fitted the floating receptors, and would be a combined protection to each cell producing them, by either completely antidoting the attacking toxin, or so modifying it that the cell would have time to prepare itself for the coming attack. This is natural immunity.

With this conception of the formation and presence of tissue antitoxins, the writer is unable to see any difference between them and opsonins.

In the successful cases of vaccine treatment of disease there is found co-incident with the rise of the opsonic index, a corresponding increase in the patient's general resistance. This can easily be understood, for if the opsonins consist of surplus receptors, the cell itself must first benefit by the treatment. And this would also make clear the improved general condition

---

(*a*) Abstract from the "Intercolonial Medical Journal of Australasia," February 20th, 1908.

sometimes found without any marked rise of the index. The stimulus given to the tissue cell has only been sufficient to raise its tone, but not enough to enable it to produce a surplus of receptors.

From this it will be seen that it is quite beside the question to say that all chemical antitoxins and bacteriolysins are specific for their respective infections, and can be of no avail for any other infection. No one disputes such statements, and were such elements the whole of the resistance in an animal, and the serum contained them alone, there would at once be an end to all discussion on the use of serums for other diseases than those for which the animal producing them had been immunised. But when the question is one of haptophore and receptor, the issue widens at once, for any element (physiological or pathological), which has a haptophore to fit the cell receptors must necessarily be able to attach itself to the cell for good or evil. This is the very element which enables the tissue to supply itself with food, and to select exactly what suits it.

A recent experience confirms such a conception of cell economy. The writer treated three stubborn chronic cases of staphylomycosis with hypodermic injections, using trypsin as a vaccine. All three were decided successes, and the cures persist. The first, a case of recurring boils, following a very severe carbuncle, had five injections, each of 30 mm. of a 2 per cent. solution of trypsin, one every second day. The constitutional effects were marked by lassitude and malaise, and the local effects in his case were pain, and a spreading erythema after the last two injections. That was six months ago, and he has not had a recurrence.

The second was a similar case, but the furuncles both preceded and followed the carbuncle. Five injections were sufficient, although when he had his fifth the negative phase was so marked that he had a painful pustule on his neck. This soon cleared up, and there has been no return. That was four months ago.

The third was a case of sycosis of five years' duration. Each injection immediately caused an exacerbation of the skin condition, so that they had to be administered at longer intervals. It was observed that the recovery from these exacerbations became more rapid after each injection as the case proceeded. His face has quite cleared up, and his general health has been much improved. He had nine injections altogether.

The first two cases, in their acute stages, were treated with anti-diphtheritic serum orally (1 dr. Parke Davis and Co.'s serum for oral use, from four to six times a day), and they did exactly the same as though they had been successfully vaccinated for the infection. The action of the serum, however, is only passive, and on its being discontinued, the cases relapsed after a short interval. To produce this element in the serum, there must have been in the toxin used for its production an element similar in action to the staphylococcus. The tryptic action of diphtheria toxin is well recognised. Hence we find that no less than three quite different agencies act alike on the same tissues, and produce the same results—the digestive element in diphtheria toxin, the staphylococcus and trypsin—all have haptophores capable of attaching themselves to the same tissues, and of producing the same results.

The writer also recently reported the result of experiments carried out on himself, in which the oral ingestion of anti-diphtheritic serum materially raised the opsonic index to the staphylococcus.

It is clear that, to obtain Ehrlich's excess cell receptors and Wright's opsonins, there must necessarily be a cell reaction, whether physiological or pathological. The cell reaction is the main element in the resistance, for on it depends the tissue antitoxins or opsonins. This cell reaction, *plus* the tissue antitoxins or opsonins, is the "tissue resistance" to which in "New Serum Therapy" (*a*) the writer ascribed the results obtained. Whether the serum was normal, or the product of acquired immunity, its action was to raise the tissue resistance, either in non-microbic conditions such as traumatism, or in infected conditions, in the diseases to which the animal supplying the serum was naturally refractory, or had been rendered so by the necessary treatment. That is, the cell reaction alone was required where the element producing the damage was non-microbic, and the cell reaction *plus* the excess cell receptors or opsonins where the pathological condition was produced by the microbic action. Hence Ehrlich's excess cell receptors or tissue antitoxins and Wright's opsonins are only part of the tissue resistance of the writer, and all harmonise.

The next question which arises is: If the tissue cells are stimulated to produce surplus receptors, by what means is the reaction in the cell initiated and maintained? Physiology of late has made us acquainted with hormones which act as stimulants on certain tissues, by which stimulus those organs are enabled to perform the function required of them. Three, at least, have been discovered and defined—the peptic, pancreatic and mammary. It is a rational postulate to say that all tissues have their own hormones, which have a selective action on the tissues for which they are produced. This obtains fully in the hormones already discovered and defined. These hormones, all of which are doubtless of glandular origin, are present under normal conditions in physiological quantity, but under pathological conditions are capable of very considerable development. That they act directly on the tissues has been definitely demonstrated in dentistry. Over 300 cases of the local injection of a solution of anti-diphtheritic serum for septic conditions were reported to the Melbourne Odontological Society, and the experience covered a period of six years, and was in the hands of various operators. All had been successful, except one case of advanced tuberculosis with pyorrhœa alveolaris. No culture had been made in that case, and the organism was unknown. The serum was of no value except on a raw surface, or injected into the tissues, and its action was entirely local. Thus the hormones in the serum had to come into contact directly with the tissues to produce the results obtained.

In the production of antitoxins, it has been found that the quantity of antitoxin present depends, amongst other factors, on the culture medium used in the growth of the organisms. If that is so with regard to the chemical antitoxin, it is quite true with regard to the hormones produced to invigorate the tissues attacked by the toxin.

The conclusions we thus arrive at are:—That resistance to infection in man and animals consists of the following elements, and that these elements are in their serums:—

(1) Antitoxin and bacteriolysin of lymphatic origin, chemical in nature, and capable of acting *in vitro*. Present only in response to the stimulus of infection.

(2) Tissue antitoxins or opsonins, consisting of excess cell receptors. Present normally in physiological quantity, and increased by pathological stimuli. With the cell reaction necessary for their production, they form that "tissue resistance" described in "New Serum Therapy."

(3) Hormones—for all tissues—present at all times, but increased by pathological stimuli. They act only in contact with the tissue cells, and not *in vitro*.

CONCLUSIONS.

The conclusions, therefore, are that:—

(1) Lymphatic antitoxins are absorbed when injected hypodermically, and act as though produced by the patient. They are not absorbed on oral exhibition.

(2) Tissue antitoxins, opsonins or surplus tissue receptors are not capable of being transferred to the patient by any known method without destroying their specific character.

(3) Hormones are changed to anti-hormones on hypodermic injection as soon as they reach the lymphatics. In the lymph spaces they act locally in contact with the tissue cells.

Rectally or orally exhibited, they act on all tissues physiologically in normal serum, and with increased power on tissues which have been pathologically affected in the animal from which the serum has been drawn.

(*a*) "New Serum Therapy." By D. Montgomerie Paton. London: Bailliere, Tindall and Cox.

The recognition of the double lines of defence, instead of one general resistance, and the consequent dual character of the resulting serum, with the necessity for each antibody to be passed directly into the system in which it originated, throws a flood of light on the whole problem of serum therapy. By it the success of the hypodermic injection of serums is rationally explained, and by it the limit of the same method and its failures are seen to be inevitable. By it also there is discovered how rational and in accord with natural methods is the oral and rectal use of serums.

By this conception it will be possible, in suitable cases, by a combination of the methods to obtain the whole resistance of the animal for the patient in hand, and as far as the writer can speak from experience in diphtheria, the results are simply ideal. For the first time we have a conception of serum therapy as a whole which blends the accepted theories and facts into harmony, and reconciles the results obtained and recorded, the character of which has hitherto made serum therapy a chaos of contradictions.

THE MILK PROBLEM,

OR THE

PRODUCTION AND DISTRIBUTION OF PURE, CLEAN MILK. (a)

By JOHN C. THRESH, D.Sc.Lond., M.D., D.P.H. Camb.,

Lecturer on Public Health, London Hospital; Examiner in Hygiene, University of London.

(Continued from page 608.)

So far, we have dealt with the more important points, the production of clean milk from healthy cows, but there are other matters to be considered if we want this pure milk delivered pure and fresh to the consumers.

As we have seen, even clean milk contains bacteria, and if this clean milk is not properly treated it may reach the consumer in anything but a satisfactory condition. These bacteria multiply with enormous rapidity unless something is done to prevent their growth, either by cooling the milk or by heating the milk so as to sterilise it or to destroy all but the spore-bearing organisms (Pasteurisation) or by adding preservatives. I do not propose to discuss the relative merits of sterilisation or Pasteurisation, or chemical treatment by the addition of preservatives. We do not want our milk Pasteurised or sterilised or chemicalised; or, if we do, we will ask for such. We want milk with all its vital properties unimpaired.

I am glad to say that many of the largest milk dealers in London, and probably the same applies elsewhere, refuse to accept any milk if the temperature upon delivery exceeds 50° F. This has been of immense benefit. Refrigerating apparatus are now found in the majority of large dairies around London and the milk is cooled immediately after being taken from the cows.

The milk, again, should be sent in locked churns, they should be under cover when in the station, and be transmitted in vans, the temperature of which can be kept at any desired degree. For short distances, and assuming the milk is thoroughly cooled in the first instance, the refrigerating van may not be a necessity, but when the milk has to travel for several hours some means of keeping it cool should be insisted upon.

Our troubles are not yet ended. When it reaches the distributor it frequently remains on his premises over night before distribution, and opportunity occurs for further multiplication of the bacteria if the low temperature is not maintained. In these cases cold storage should be provided and the churns placed therein until the carts are ready to go their round. This is done at the present time by some dairy associations, and I am not aware that they charge more for their milk than other dealers.

Milk which has been delivered to the smaller dealers is often kept under very unhygienic conditions, occasionally under conditions which render dangerous contamination possible, if not probable, and when sold from the shops it is often kept in open vessels exposed to dust and flies and where it may absorb emanations from other articles in the vicinity, and milk has an extraordinary capacity for absorbing volatile odorous matters.

In all shops from which milk is sold the milk should be kept in properly-covered vessels, so that flies and dust cannot gain access, and if things besides dairy produce are sold the vessels should be stored in a special cupboard or case capable of being kept cold in summer, and nothing but dairy produce should be kept in the cupboard.

Having procured our clean milk and delivered it to the consumer, it is still liable to serious pollution or deterioration in the home. I think it may be found possible to deliver an unpolluted milk—a milk which would form a wholesome diet to our children, but amongst the poorer classes how long will it remain in this condition? It has been seriously argued that the greatest danger arises from home pollution. I am unable to agree with this, but it is certain that in the houses of the poor it is almost impossible to keep milk many hours in a wholesome condition. There is no cool larder and the mother's ignorance is too great for her to recognise the necessity for taking what to us are obvious precautions. The people perish for lack of knowledge. We can only hope for an improvement by the better education of the rising generation. Some impression may be made upon the present generation by means of the Press and local health associations, and by the influence of health visitors, female sanitary inspectors, and others who are engaged in spreading the gospel of health, but our chief hope is centred on the education of the future mothers—on our children.

In this connection I may suggest that a crusade against the common house-fly might be of greater advantage to the community than the crusade against rats, as the former are really the more dangerous disease carriers in this country.

Before giving you briefly my views upon the means necessary for effecting the reforms I have indicated, may I say a few words which may be of interest to the farmers, for unless we can convince the farmer of the reasonableness of our demands and of their practicability, we shall meet with the most strenuous opposition. I assert, therefore, that not only are our demands reasonable and practicable and in the interests of the general well-being of the community, but that they are actually serving the best interest of the great dairy industry.

I want in the first place to show them that the amount of milk used at the present time is only a fraction of the amount which should be used, and which will be used, when a purer milk is available.

An old student and assistant of mine, Dr. Sowden, the Medical Officer of Health for East Ham, with a population of over 100,000 persons, chiefly of the working class, has made a careful estimate of the amount of fresh milk and other forms of milk used in that borough. He obtained the information through the milk dealers and from the retailers of tinned milks.

He found that the amount of fresh milk used daily averaged a little less than 3oz. per person, or one pint per person per week. I have reason to believe that in many districts it is even less than this. The 100,000 people used 960 dozen tins of condensed whole milk and 1,800 dozen tins of condensed separated milk per week. Assuming that each tin represents 1 quart of milk, this gives a weekly consumption of ¼ pint of whole milk per person, and ½ pint of skimmed milk per person. The total consumption of milk of all kinds is under 2 pints per person per week, and of this very nearly half is imported milk, and over one-fourth is skimmed milk.

The importation of milk in tins is an enormous and increasing industry, and in our towns it seems probable that nearly half the milk consumed is this imported variety, yet its cost is two or three times that of fresh milk of similar quality.

If by gaining the confidence of the public this sale could be decreased it would be of very great advantage to our milk producers, and what is of even greater importance, it would be to the advantage of the poor. Dr. Sowden's results confirm the conclusions of others—namely, that few deaths from diarrhœa occur amongst breast-fed infants, and that the largest proportion occur amongst those fed (? starved) on the tinned milk; this fact wants bringing home to every mother in the country.

(a) Abstract of paper read before the Birmingham Branch of the Incorporated Institute of Hygiene, March 30th, 1908.

Besides the competition of the tinned milk producer, another rival has to be encountered, the manufacturer of dried milk. This dried milk is of recent introduction and the demand for it is rapidly increasing. I know of one medical officer of health who is supplying it from the Municipal offices at a very low price, and he informs me that children fed upon it have done remarkably well, and that in the diarrhœal season few of those who used it suffered from diarrhœa, and that many children who had been attacked and were quickly placed on the new diet of dried milk made rapid recoveries. One gentleman occupying a prominent position in my county recently said that dairy farmers were between the devil and the deep sea. The devil being myself, who, it was alleged, wanted money, which the farmers could not afford, spending on the production of pure milk, and the deep sea being my friend the Medical Officer of Health, who, to save the lives of infants, was urging parents to feed them on dried imported milk.

I think that I have said enough to show that if the dairy farmer does not realise the seriousness of the position and make some effort to meet the demands we are making, his industry will become a decaying one, both prices and demand will decrease, and ruin stare him in the face.

With the greatest possible benefit to ourselves we could consume from four to ten times as much milk as we do at present. Is it not, therefore, to the advantage of the dairyman to encourage us to do so?

Do the farmers want to prevent the competition with Municipalities, so many of whom are establishing milk depôts? If so, let them supply us with pure milk.

We are now dependent upon the farmers on the Continent for much of our cheese and butter, and unless the farmers bestir themselves we shall soon depend upon them for much of our milk also. A little energy and a little enterprise and we may retain this national industry, whereas apathy and delay may result in our losing it. It is chiefly for the farmer to say whether we lose or retain it.

Finally, allow me to summarise our demands and to indicate how they may be met. This will concentrate our thoughts upon the more important points in the problem and possibly aid us in any discussion which may follow the address.

Firstly, there is the veterinary inspection of all milk cows and the elimination of all diseased cows, and more especially of cows suffering from tuberculosis. For this purpose veterinary inspectors must be appointed, and if they are to be beyond the effect of local influence, they must be appointed by some central authority, the Department of Agriculture, the Local Government Board, or the County Councils, and they must be paid such a salary that they can devote their whole time to their duties.

Animals likely to yield disease-producing milk must be promptly dealt with. They must not be allowed, as at present, to be sold and sent into some other district to be used as milk cows there. They must be slaughtered, and, under certain circumstances, I think some compensation should be paid to the farmer. This is a very vexed question, and, though very important, it is not one which we can adequately discuss at this meeting.

Secondly, there is the absolute necessity for uniform regulations with regard to the ventilation, cleanliness, etc., of cow-sheds, and with regard to the cleanliness of the operations necessary for the collection of milk. These regulations must apply to the whole country, and not depend upon adoption by local authorities. I am of opinion that local authorities should be held responsible for seeing that they are carried out, but that County Councils should act as supervising authorities, and have powers which would enable them to see that they were carried out.

The veterinary inspector might report to these local authorities all cases in which he found water supplies defective, cows ungroomed, or when he had reason to believe any of the regulations were infringed, and if at a subsequent visit he found that the local authority had not taken action, he should then report to the authority by whom he is appointed.

Thirdly, all milk not sold locally and within three or four hours of being drawn from the cow, should be cooled down to 40° F., and, if sent away by rail, placed in locked churns, and the railway companies should be compelled to deliver this milk at its destination at this temperature.

Fourthly, all premises used for producing milk, cooling milk, storing milk, and for the sale of milk, should be registered, and every person carrying on the trade of a cowkeeper or milk dealer be licensed. Registrations and licenses should be renewable annually, and be withdrawable at any time for persistent breach of regulations.

Fifthly, and lastly, the sale of milk from a diseased cow, and the sale of unclean milk, should be made an offence of a far more serious character than the mere adulteration of milk by the addition of water, or preservatives, or the abstraction of fat.

I do not think there is anything unreasonable in these demands, and I believe that all are feasible, and that all will in the near future be conceded.

The result of the reforms here suggested cannot but be a great decrease in the rate of infantile mortality and a great benefit to British agriculture. I know of no two objects which could be of greater interest to you as citizens of a great city, and as subjects of a great Empire, whose continued prosperity depends so much upon agriculture and upon the rearing of a virile race.

EMPYEMA IN CHILDREN.

By STEPHEN J. ROSS, M.D., Ch.B.,

Assistant Surgeon to the Bedford County Hospital.

Empyema occurring in children is by no means a rare condition, but is frequently overlooked. The most frequent symptoms calling attention to the condition are that a child who has passed through an attack of pleuro-pneumonia, or broncho-pneumonia, does not satisfactorily convalesce; the cough and the fever persist, then fluid in the pleural cavity is discovered. Or a child has an indefinite illness, followed by marked emaciation. This leads to an examination of its chest, and the discovery of fluid in one of the pleural cavities. The organisms present in empyemata may be: (1) the pneumococcus; (2) streptococci and staphylococci; (3) tubercle bacilli.

Etiology.—Pleuro-pneumonia and broncho-pneumonia are not infrequently the precursors of empyema. Scarlet fever, measles, diphtheria, and typhoid, are sometimes complicated by empyema.

Symptoms.—The onset of empyema is often very insidious—the history being a deferred convalescence from pneumonia, and frequently we note very marked wasting.

In other cases the onset is very acute, and if effusion be rapid the probabilities are in favour of empyema.

Physical Signs.—The breathing is rapid and shallow. There may be bulging of the intercostal spaces on the affected side.

On palpation, the apex beat of the heart may be displaced to the right or left according to the side upon which the effusion occurs. This is a very important sign, as many of the other signs are equivocal. On percussion, we find dulness; the dulness is wooden, and absolute; percussion must be light.

Auscultation.—Breathing may be tubular or bronchial. Friction sounds may be present; vocal fremitus is often increased.

The breath sounds on the normal side of the chest are exaggerated.

Treatment.—This resolves itself into aspiration or resection of part of a rib. The cases I am now about to record will indicate the usefulness of the minor or major operation. While deciding as to treatment, we must remember that young patients bear shock badly, and that an anæsthetic must not, without careful consideration, be given.

Case I.—I saw a child, æt. 4, who was suffering from wasting which was supposed to be due to consumption. Upon examining his chest, I found an effusion into the left pleura; the apex beat of the heart was situated in the epigastrium. I introduced an exploring needle into the sixth left intercostal space and withdrew pus. The causative organism I found to be the pneumococcus. The child was very feeble; his pulse was very frequent and weak; his respirations were very laboured. He would not stand an anæsthetic, so I aspirated his chest, withdrawing a pint of thick pus. He made an uninterrupted recovery. When aspirating a chest it is always wise to use a needle with a wide bore. There was no re-accumulation.

The second case was that of a child, æt. 3, who had been ill six weeks with pneumonia. His temperature when I saw him was 103°, and the right side of his chest was full of fluid, the dulness extending to his right clavicle. Under ACE, I resected part of his eighth rib, put in a large drainage tube, and he made an uninterrupted recovery.

A girl, æt. 8, had an empyema upon the left side. This I drained in the eighth intercostal space behind and below the inferior angle of the left scapula. For ten days she improved markedly. Then her temperature rose to 103° and I thought she had some fresh infection. I examined the pus and discovered streptococci. Above my incision I discovered a patch of dulness, and, introducing forceps through my original wound, 3 ounces of pus escaped. I injected her with 5 c.c. of anti-streptococci serum, and her temperature fell from 101° to normal. The following morning I gave her a second injection of 5 c.c. She made an uninterrupted recovery. The point of interest in this case lay in the fact that six weeks previously she had a septic tonsillitis, doubtless the origin of the empyema.

My final remarks must be:—

1. If a child be brought to us on account of wasting, never omit to examine the chest.
2. If the child be too feeble to stand the operation of resection of ribs, remember that aspiration sometimes results in cure.
3. If we have a child under our care suffering from pneumonia whose convalescence is protracted, we must never forget to keep a watchful eye for the development of fluid.
4. If after drainage the patient's progress be unsatisfactory, we must remember that loculated collections of pus are not infrequent.
5. It is always necessary to examine the pus for the causal organism. If the pneumococcus be found the outlook is favourable. If, streptococci, the injection of anti-streptococci serum will hasten convalescence. If the tubercle bacillus be discovered the outlook is very unfavourable indeed.

THE SURGICAL TREATMENT OF CHRONIC DYSENTERY

(COLITIS ULCEROSA CHRONICA).

By Prof. H. STEINER, M.D.,

Berlin.

[Specially Reported for this Journal.]

The swing of the pendulum that has taken place in intestinal surgery in general during the past ten years seeming to justify an attempt at surgical measures, at the suggestion of my colleague, Prof. Boas, I lately undertook the operative treatment of a case of chronic dysentery that was apparently incurable, and to all appearance lost.

The idea of relieving the ulcerated parts of the bowel from the passage of fæces was the less remote, as an analogous treatment of the rectum—the site of syphilitic ulcers—by making an artificial anus in the sigmoid flexure had been brought forward.

The two clinical histories, which I sketch in outline, show that a success was obtained only by great patience on the parts of both patient and surgeon. Especially the perfecting of a system of washing out the bowel—in both peristaltic and anti-peristaltic directions—the temperature and force of the stream required many trials before we succeeded in carrying out the procedure in a painless manner.

The first case was that of a lady, æt. 27. The disease began nine years before I saw her, and its progress had been gradual and creeping. Frequent attacks of diarrhœa alternated with periods of constipation; at last the evacuations were of a pronounced loose character and were very frequent. Slight febrile attacks occurred, with abdominal pain; even to the eye the stools consisted of blood and pus mixed. The microscope showed mucus, pus, blood, and numerous Charcot-Leyden crystals. Tubercle bacilli and amœbæ were sought for in vain. The patient was a virgo; there was no trace of leucorrhœa.

After Professor Boas had had the patient under treatment for three years with strict diet, and all the known internal remedies, with washings-out of the bowel as well, without any good result, he decided to send her to me for operation. He was led to this through a favourable report on the operative treatment of the condition from America. The condition of the patient on admission into the Klinik was very unfavourable. She looked pale and suffering, had a hectic fever, and was so weak that she could scarcely stand. Day and night the copious evacuations were watery, and even to the naked eye contained mucous, blood, and pus; in addition to this there were colicky pains along the course of the colon. The abdomen was slightly distended and tender to pressure. Examination by the rectum showed only normal conditions.

Under an anæsthetic I made a large cæcal anus præternaturalis, the opening just below the valvula Bauhini. When the abdomen was open the small intestine was seen to be intact; the serosa of the colon was swollen in places.

After the artificial anus had begun to act the temperature fell, and the colicky pains ceased. The passage of the fæcal matter by the colon became less frequent and less in amount.

The real treatment now began, in daily washing out of the colon through the cæcal anus; 4 or 6 litres of water of the body temperature—a lower temperature set up by the colicky pains—were allowed to run through every day. When in this way all the stagnating secretions from the bowel and ulcerated surfaces had been washed away, and the water came away clear, a medicated wash was passed in (also in the anti-peristaltic direction) in which mild protargol solutions were made use of. These washings-out, which I looked on as the chief curative agents, were kept up seven and a half months, latterly every second day, as up to this time microscopic examination still showed the presence of pus and Charcot-Leyden crystals, but in diminishing quantities.

When, from the character of the water that came away after the washing it appeared probable that the intestinal ulcers were healed, and about nine months after the operation, I blocked up the artificial anus with plugs of lint steeped in vaseline, and in this way obtained a passage of fæces by the rectum. This trial of the natural passages continued for about five weeks, and as it showed that the fæces could pass without reaction, the artificial anus was closed after it had been in action for about a year.

Since that time about six years have now elapsed. The patient has gained about 60 pounds in weight, she is perfectly well, and carries on her affairs with satisfaction.

As the history of the second case, independent of its duration, is very much like the first, I need only mention the essentials. The patient, a female, æt. 30, came under my care in April, 1904. Since July, 1903, she had suffered from diarrhœa which first came on during a pregnancy, and was at first taken but little notice of. After the labour the diarrhœa could not be controlled; the patient had also abdominal pains and fever. Professor Boas made a diagnosis of ulcerative colitis.

In the beginning of January, 1904, a cæcal anus was made by Professor Israel. In April of the same year the patient was discharged from hospital, when I began to wash out the bowel carefully, as in the first case. The patient weighed 85 pounds. Most of the evacuations were passed per *vias naturales*, and contained a good deal of blood and pus, and numerous Charcot-Leyden crystals. After daily washings-out for two months, the colon was brought into the desired condition, and after testing the function by temporarily blocking up the artificial anus, it was finally closed in July. The patient very quickly put on 40 pounds in weight.

Neither of the patients were restricted as to diet, but the colon or cæcum, or both, are very susceptible to chills, which sometimes appear when the flannel binder is left off. The tendency to constipation then takes another turn, but without the stools showing the ominous mixture of former times. The condition, moreover, passes away as soon as the fault had been rectified. Both the patients have taken up their former activities since leaving the Klinik, and may both be considered as quite recovered. It may be mentioned in addition that neither amœbæ nor tubercle bacilli were ever seen in the stools, nor had either of the patients ever had syphilis.

As regards other methods of operation, proposed and carried out, that of opening the colon at the sigmoid flexure should be absolutely and unconditionally rejected, as the autopsy *in vivo* has shown that the ulcerative disease, though principally seated in the transverse colon, also affects the ascending portion.

Appendicostomy, *i.e.*, opening of the vermiform appendix and suturing it to the abdominal walls, also fails to fulfil the requirements of rational treatment—shutting the affected parts off from the passage of fæces, and allowing free washing-out. Another method, the formation of a cæcal anus, with complete separation of the ileum, and suturing it to the abdominal walls, has the advantage that no trace of fæcal matter can find its way into either cæcum or colon; but it has one great disadvantage, that it does not allow a testing closure of the artificial anus after presumed healing of the ulcers, but that, after they have healed, at a point of time which it is very difficult to determine—a second very serious operation is called for, whilst closure of the cæcal anus does not even require general narcosis.

I would most decidely pronounce against the ileo-sigmoideal anastomosis—the separation of the ileum from the cæcum, with transplantation of the small intestine into the sigmoid flexure, where a cæcal anus for the passage of the stagnating discharges from the colon must also be made.

I had the opportunity of treating for a long time a patient operated on in this way elsewhere. The anti-peristaltic washings were exceedingly agonising, as part of the washing-out fluid got into the implanted ileum and set up violent colic. Washings out in the peristaltic direction did not completely remove the collections of pus that flowed back into the cæcum and there stagnated. As the patient also suffered from nephritis and was reduced to a skeleton, the very serious operation performed in the two previous cases would have been dangerous; it was therefore declined.

In view of the recovery of my two very serious cases, I can recommend the simple procedure which was adopted, and which consists of the following:—

1. The formation of a large cæcal artificial anus, close to and slightly below the valvula Bauhini.
2. Free anti-peristaltic washings-out of the whole colon (6 to 10 litres).
3. After the washings have become clear, a mild medicated solution of iodine or protargol.
4. After the ulcers in the colon have healed, testing of the bowel by allowing the passage of fæces (blocking up of the cæcal anus with vaseline tampons).
5. After it has been shown in this way that the ulcers have really healed, operative closure of the artificial anus.

Lastly, I would recommend the method in other serious diseases of the colon in which medicines have failed, in place of shutting off of the colon, as has been recently proposed, to which it is preferable in every way.

CLINICAL RECORDS.

A CASE OF RENAL CALCULUS IN A CHILD.

By R. C. DUN, C.M., F.R.C.S.,

Honorary Surgeon to Liverpool Infirmary for Children.

The patient was a girl, æt. 6. For two years she was reported by her mother to have been "ailing with stomach pains," and, from time to time, to have passed blood in her urine. The hæmaturia would appear to have sometimes been considerable, as the water was "dark red." For three months before I saw the child there was no history of blood having been passed. The abdominal pain had never been very severe; it was intermittent, not aggravated by movement, and was always referred to the region of the bladder. At no time had it been accompanied by vomiting.

When first seen in the out-patient department of the Liverpool Infirmary for Children the child looked pale. The temperature was normal. There was some pain and tenderness on palpation in the hypogastrium. No pain was elicited or swelling discovered during the examination of the kidney regions. The urine was normal, according to the ordinary chemical tests. No microscopic examination was made. The bladder was sounded for stone with negative result.

Five days later (April 3rd, 1907) the child was admitted to my ward. The urine had not been discoloured since I first saw her, and the abdominal pain was much diminished. After a few days' rest in bed the girl became quite free from pain. The urinary sediment was daily examined; a few red blood corpuscles were constantly seen under the microscope. There were no pus cells, and on one occasion only were uric acid crystals seen. The usual chemical tests revealed no abnormality in the urine. The kidney regions were frequently and carefully palpated; as a rule no discomfort was experienced, but on one or two occasions slight tenderness appeared to be present about the right kidney. There was no appreciable renal enlargement. For a week the child was kept in bed; she was then allowed up, and encouraged to play about in the ward, but no aggravation of her symptoms resulted.

On April 19th an X-ray photograph was kindly taken for me by Dr. Thurstan Holland. A very definite shadow was seen in the right kidney region, which Dr. Holland had no hesitation in pronouncing to be that of a renal calculus.

Three days later I operated. The right kidney was exposed by a lumbar incision, and brought out through the wound. A hard, small swelling was readily palpable towards the upper pole. On incising the kidney substance the knife at once came in contact with a stone, which was removed without difficulty from the upper calyx. No pus was present. Search was made for other calculi in the lower calyces and ureter, but none were found. The hæmorrhage was inconsiderable. The kidney substance was stitched with buried catgut sutures, and the capsule re-united. The superficial wound was closed, space being left for a drainage tube passing down to the kidney.

The stone removed was smooth, irregularly triangular in shape, and composed of uric acid. It weighed 6 grs.

The child made a satisfactory recovery. The drainage tube was removed on the fourth day, and there was never any leakage of urine through the wound. There was some hæmaturia for a week, after which time all blood disappeared from the urine.

I have seen the child at intervals since the operation. She has had no pain, and I have been unable to find any blood corpuscles in her urine. Uric acid and oxalate of lime crystals have sometimes been present, and appropriate medical treatment is being given for this condition.

I report this case because renal calculi are very rarely met with in children, because the symptoms were of a most indefinite nature, and for the purpose of emphasising the importance of radiography as an aid to diagnosis.

How seldom children suffer from stone in the kidney can be gathered from the following statements.

Holt, in his work on "Diseases of Infancy and Childhood," says that, although minute granules of uric acid are frequently found post-mortem in the kidneys of children, stones of any size are very rarely met with.

Ashby and Wright, in the last edition of their book, state that they have only operated on two or three cases.

Henry Morris, in 96 operations for renal calculus, had no patient under 10 years. The same authority, in a series of 283 operations for kidney stone which he had collected, found that only one had been performed on a child under 10.

In the reports of the Society for the Study of Disease in Children, published from 1901, only 5 cases of renal calculus are included.

In my own seven years' experience at the Liverpool Infirmary for Children I have met with one other case of kidney stone.

The slight and indefinite symptoms in the present case are worthy of notice. The only pain complained of was inconsiderable, and referred to the bladder. The tenderness on deep palpation of the right kidney was so indefinite and so rarely to be elicited that it proved of little value as a diagnostic sign. The blood in the urine was so small in quantity that it could only be recognised microscopically, though there had been a definite previous history of hæmaturia, and crystals were only seen in the urinary deposit on one occasion. There was no kidney enlargement, and the pain and hæmorrhage were unaffected by movement.

Such symptoms could at the most only suggest the possibility of a renal calculus being present. In my opinion they did not justify an exploratory operation, as the general health of the child was but little affected. The radiographer's art made the diagnosis certain, and enabled me to remove the stone before any serious damage to the kidney substance had resulted.

A study of the few reported cases of renal calculus in children shows that practically all of them have come under the surgeon's care suffering from symptoms of hydro- or pyo-nephrosis. Does not this mean that the earlier signs of kidney stone have been overlooked? How slight those signs may be is demonstrated in the present case. Let us be on the look-out for such symptoms, and keep in our minds the great help in diagnosis which may be obtained from radiography. For it is only in this way that an early diagnosis can be made, and the affected kidney saved from serious and, it may be, irremediable damage.

SPECIAL REPORTS.

GENERAL MEDICAL COUNCIL.

EIGHTY-SEVENTH SESSION.

(Report of Session concluded from our last issue.)

SIXTH DAY.—Monday, June 1st, 1908.

The President, Dr. MacAlister, in the Chair

The whole of the meeting was taken up with the further consideration of the case of John Papa Nicolas, adjourned from Saturday, May 30th, 1908.

Mr. Hemming intimated that he had a further objection which he had put in writing, and which he handed in.

The President announced that the document was not an objection, but a protest against the action of the learned Legal Assessor, and that the Council would have an opportunity to place it on its records if it thought fit.

Witnesses for the defence, Lizzie Becker (nurse) and Mr. Howard Wallace (shipbroker), examined by Mr. Hemming and briefly cross-examined by Mr. Neilsen.

Mrs. Edith Ellis, examined by Mr. Hemming, and briefly cross-examined by Mr. Neilsen, also answered questions by the Legal Assessor.

Mr. Cordery (surveyor) and Mr. P. J. Holt (surveyor) were examined by Mr. Hemming and cross-examined at some length by Mr. Neilsen. Mr. Holt also answered questions by the Legal Assessor.

Mr. Hemming called Mrs. Emily Holt as a witness, and examined her. Mr. Neilsen did not cross-examine the witness.

Mr. Hemming called Miss Nellie Taylor as a witness, and examined her. She was cross-examined by Mr. Neilsen, and answered questions put to her by the Legal Assessor.

Mr. Hemming called Mrs. Phœbe Adelaide Taylor as a witness, and examined her. Mr. Neilsen did not put any questions to the witness.

Mr. Hemming called Mrs. Isabella Lydia Burton as a witness, and examined her. She was cross-examined by Mr. Neilsen.

Mr. Hemming called Mrs. Rebecca Baker as a witness, and examined her. Mr. Neilsen did not cross-examine the witness.

Mr. Hemming called Mrs. Rose Rimmell as a witness, and examined her. She was cross-examined by Mr. Neilsen, and answered a question put to her by the Legal Assessor.

Mr. Hemming called Mrs. Kathleen Burton as a witness, and examined her. She was cross-examined by Mr. Neilsen.

Mr. Hemming called Mrs. Catherine Dalbin as a witness, and examined her as to a statutory declaration which he proposed to put in, annexing a statement signed by about eighty patients of Mr. Papa Nicolas who had not been canvassed by him. Mr. Neilsen objected to this being done. The Legal Assessor advised that the document should be admitted.

Mrs. Dalbin was cross-examined by Mr. Neilsen. She was re-examined by Mr. Hemming, and answered questions put to her by the Legal Assessor. She also answered questions put to her through the Chair by members of the Council.

Mr. Hemming obtained leave to put a further question, through the Legal Assessor, to the witness.

Mr. Hemming then tendered himself as a witness in order to put in the draft of the declaration which had been put in during the examination of the last witness.

Mr. Neilsen cross-examined the witness, who also answered questions put to him by the Legal Assessor. He also answered a question put to him by a member of the Council, through the Chair.

On a motion by Dr. Norman Moore, which was seconded by Dr. Latimer, and agreed to, it was decided that the Council should meet at 11 a.m. on the morrow.

Other witnesses, Miss Lillie Cullen, Mr. H. E.

Lavallin, and Miss Kate Cullen, were examined and cross-examined.

Mr. J. P. Nicolas then went into the witness-box, and was examined by Mr. Hemming, principally with regard to the period during which he (Mr. Nicolas) had acted as assistant to Mr. Atkinson. Mr. Hemming put in ten testimonials given to Mr. Papa Nicolas, some of which he read.

The Council adjourned before the end of Mr. P. Nicolas's examination.

SEVENTH DAY.—Tuesday, June 2nd, 1908.

The President, Dr. MacAlister, in the Chair.

The Chairman of the Business Committee announced that, in view of the late period of the Session, Dr. Langley Browne had withdrawn a motion of which he had given notice, and the consideration of which would take some time.

Moved by Dr. Norman Moore, seconded by Mr. Thomson, and agreed to:—"That the Office Site Committee, consisting of the President, the two Treasurers, and the Chairman of Business, should be empowered, in consultation with the Solicitor, to deal with any application for a licence to assign or underlet the existing lease of 16, Hanover Square, and, if necessary, to affix the corporate seal to any licence."

Moved by Dr. McVail, seconded by Sir Christopher Nixon, and agreed to:—"That the two reports of the Examination Committee be received and entered as appendices in the minutes."

The reports dealt with the medical examinations of Boards and Universities of the United Kingdom, and of Indian and Colonial Universities, and the Assistant Examiners had expressed themselves as satisfied with regard to the manner in which the examinations were conducted.

Moved by Dr. Norman Moore, seconded by Sir John Moore and agreed to:—"That the Report of the Pharmacopœia Committee be received and entered on the minutes."

The report deals with the sales of the B.P. and Addenda, and also referred to a recent publication which appeared to the members of the Pharmacopœia Committee to infringe the statutory rights in the Pharmacopœia.

The Council resumed the consideration, adjourned, on the motion of Mr. Morris, from Tuesday, May 26th, 1908, of the Report of the Executive Committee in regard to the duties of the Assistant Examiners to the Apothecaries' Hall, Dublin. With reference to recommendation, it was moved by Sir Thomas Myles, and seconded by Dr. Saundby:—"That it be amended by the insertion after the words 'held by' the words 'the Society of Apothecaries of London and the.'"

The Council then further considered the case of John Papa Nicolas, adjourned from the previous day.

Mr. Hemming resumed his examination of Mr. Nicolas, and put questions to him relative to the correspondence regarding his case which had passed between the Registrar and himself, and between the Solicitor to the Council and Mr. Hemming. He also took him, *seriatim*, through the statutory declarations which had been put in by the complainants, and examined him as to the accuracy of the statements made by the declarants in the documents and in the witness-box.

One o'clock having arrived, the examination of the witness was suspended.

Moved by Mr. Tomes, seconded by Mr. Morris, and agreed to:—"That the Report of the Dental Education and Examination Committee be received, entered in the minutes, and adopted."

Moved by Dr. Langley Browne, seconded by Dr. Mackay, and agreed to:—"That the Interim Report from the Unqualified Practice Prevention Committee be received, and entered in the minutes."

Moved by Sir Hugh Beevor, seconded by Dr. Norman Moore, and agreed to:—"That the Report of the Students' Registration Committee be received, entered in the minutes, and approved."

Moved by Dr. Latimer, seconded by Dr. Saundby, and agreed to:—"That the Executive Committee be requested to consider and report on the course to be followed in the case of practitioners who apply to be removed from the *Medical* or *Dentists' Register*."

Moved by Mr. Tomes, seconded by Dr. Little, and agreed to:—"That the Report of the Finance Committee be received, entered in the minutes, and adopted."

Moved by Dr. Norman Moore, seconded by Sir Christopher Nixon, and agreed to:—"That the nominations of the Branch Councils for the Examination Committee be adopted."

The following members had been nominated by:—(*a*) The English Branch Council: Dr. Pye-Smith, Mr. Young, Dr. Caton. (*b*) The Scottish Branch Council: Sir Thomas Fraser, Dr. Finlay, Dr. McVail. (*c*) The Irish Branch Council: Sir John Moore, Sir Charles Ball, Dr. Kidd.

Moved by Dr. Norman Moore, seconded by Sir Christopher Nixon, and agreed to:—"That the nominations of the Branch Councils for the Education Committee be adopted."

The following members had been nominated by:—(*a*) The English Branch Council: Dr. Norman Moore, Sir G. Philipson, Sir John Williams. (*b*) The Scottish Branch Council: Dr. Mackay, Sir John Tuke, Dr. Lindsay Steven. (*c*) The Irish Branch Council: Sir Thomas Myles, Sir C. Nixon, Dr. Little.

Moved by Dr. Norman Moore, seconded by Mr. Thomson, and agreed to:—"That the nominations of the Branch Councils for the Public Health Committee be adopted."

The following members had been nominated by:—(*a*) The English Branch Council: Dr. Cocking, Mr. Power, Dr. Langley Browne. (*b*) The Scottish Branch Council: Dr. Norman Walker, Dr. Lindsay Steven, Dr. McVail. (*c*) The Irish Branch Council: Sir John Moore, Dr. Adye-Curran, Dr. Kidd.

Moved by Dr. Norman Moore, seconded by Mr. Morris, and agreed to:—"That the following be the members of the Pharmacopœia Committee:—The President, Chairman; Dr. Norman Moore, Dr. Barrs, Sir John Moore, Sir Geo. Philipson, Sir Thomas Fraser, Dr. Little, Dr. Caton, Dr. McVail."

Moved by Dr. Norman Moore, seconded by Mr. Thomson, and agreed to:—"That the following be the members of the Finance Committee:—Mr. Tomes, Chairman; Mr. Morris, Sir John Tuke, Dr. Little."

Moved by Dr. Norman Moore, seconded by Mr. Thomson, and agreed to:—"That the following be the members of the Dental Committee:—The President, Chairman; Mr. Morris, Sir Thomas Myles, Mr. Tomes, Mr. Hodsdon."

Moved by Dr. Norman Moore, seconded by Mr. Thomson, and agreed to:—"That the following be the members of the Dental Education and Examination Committee:—Mr. Tomes, Chairman; Mr. Morris, Sir Thomas Myles, Dr. Lindsay Steven, Sir Charles Ball, Dr. Finlay."

Moved by Dr. Norman Moore, seconded by Sir John Moore, and agreed to:—"That the following be the members of the Students' Registration Committee:—Sir Hugh Beevor, Chairman; Dr. Norman Moore, Dr. Adye-Curran, Sir John Batty Tuke, Sir Christopher Nixon, Dr. Mackay."

The Council proceeded to ballot for the election of the Executive Committee and the Penal Cases Committee.

Mr. Hemming resumed his examination-in-chief of Mr. John Papa Nicolas. Mr. Papa Nicolas was cross-examined by Mr. Neilsen.

In the course of his cross-examination, Mr. Neilsen asked a question in regard to the witness's statement to his solicitor as to the terms of the proposed partnership with Mr. Atkinson, to which Mr. Hemming objected. The Legal Assessor admitted the question. Mr. Hemming requested that his objection should be recorded, and this was agreed to.

At 4 o'clock p.m., the cross-examination of Mr. Papa Nicolas was suspended.

The President announced that the following had been elected members of the Executive Committee:—Sir Hugh Beevor, Dr. Pye-Smith, Mr. Young, Mr. Tomes, Sir John Tuke, Dr. McVail, Sir John Moore, Sir Charles Ball. And that the following had been elected members of the Penal Cases Committee:—

Dr. Saundby, Mr. Tomes, Dr. Finlay, Sir Christopher Nixon.

Mr. Neilsen then resumed and completed his cross-examination of Mr. Papa Nicolas. Mr. Papa Nicolas was re-examined by Mr. Hemming, who asked Mr. Atkinson and Dr. Hugh Woods to produce the bill which Mr. Papa Nicolas had sent in to Mr. W. Tacon, and on which he had been cross-examined. Mr. Neilsen stated that it was not in the possession of the complainants. Mr. Hemming requested that his application should be recorded. Mr. Papa Nicolas answered questions put to him by the Legal Assessor in regard to the alleged payment of five shillings to a witness, which had been asserted by him in the course of cross-examination. He also answered other questions put to him by the Legal Assessor.

Mr. Hemming then called Mr. Edward Woods as a witness, and examined him. Mr. Woods was cross-examined by Mr. Neilsen, and re-examined by Mr. Hemming.

Moved by Dr. Norman Moore, seconded by Mr. Thomson, and agreed to:—"That Standing Order IV., 2, be suspended in order that the Council may meet at 10.30 o'clock a.m. to-morrow."

Mr. Hemming then called Mrs. Mary Ann Richardson as a witness, and examined her. She was cross-examined by Mr. Neilsen, and answered a question put to her by the Legal Assessor.

Mr. Hemming applied for information as to how he should deal with the affidavit of a witness who was too ill to appear.

The Legal Assessor advised him to show it to Mr. Neilsen with a view to its being put in without opposition, if possible, and to obtain a medical certificate as to the inability of the witness to attend.

The Council then adjourned.

EIGHTH DAY.—Wednesday, June 3rd, 1908.

The President, Dr. MacAlister, in the Chair.

Nearly the whole of the day (10.30 to 1, 1.30 to 6.45) was devoted to the further hearing of the case of John Papa Nicolas, adjourned from the previous day.

Mr. Hemming first called and examined a few more witnesses, who denied having been canvassed by Mr. Nicolas, and then he (Mr. Hemming) made his speech for the defence. This speech lasted nearly five hours, and dealt with the entire case, mostly questioning the credibility of the complainants and their witnesses.

Mr. Neilsen then answered, and the Legal Assessor said a few words.

Strangers having been requested to retire, the Council deliberated *in camerâ* for an hour.

On the readmission of strangers, the President called Mr. John Papa Nicolas, and announced to him that the Council had found him guilty of infamous conduct in a professional respect, and that the Registrar had been ordered to erase the name of John Papa Nicolas from the *Medical Register*.

Mr. Hemming then asked that the Registrar should be ordered to suspend action for a month.

The President answered that Mr. Hemming must make an application in writing.

The Council postponed the consideration of the Report from the Executive Committee in regard to proposed alterations in Chapters XIV. and XV. of the Standing Orders; also the consideration of the Report of the Executive Committee in regard to the duties of Assistant Examiners to the Apothecaries' Hall, Dublin, with motion and amendment thereon; also the motion by Dr. Adye Curran, seconded by Dr. McManus:—"That reports by the Assistant Examiners in Surgery of the Apothecaries' Hall of Ireland be discontinued for the present"; also the consideration of a resolution of the Standing Committee with reference to Standing Order IX., 3.

A motion of Mr. Morris, seconded by Mr. Tomes:—"That the minutes which have been printed and circulated be taken as read, instead of being read *in extenso* by the Registrar," was referred to the Executive Committee.

The Report from the Public Health Committee was received and entered on the minutes.

The motion of Dr. Mackay, seconded by Dr. Norman Moore, "That the Chairman of the Education Committee be authorised to communicate to the Licensing Bodies for verification of the statistics therein contained, an Interim Report of the Education Committee on various proposals submitted to them referring to the curriculum in medicine," was adopted.

The Report of the Education Committee was adopted. This report dealt with the reply of the Council to a resolution adopted by members of the Medico-Legal Society with regard to the administration of anæsthetics.

The motion of Mr. Tomes, seconded by Dr. McVail, "That, together with the reports of the Dental Committee, the prints of the documents and evidence placed before the Committee be circulated to the members of the Council," was adopted.

Mr. Henry E. Allen was appointed General Registrar.

The Council then rose.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 7th, 1908.

Diabetic Retinitis.

Whereas retinitis in Bright's disease is accepted by all, that observed in the course of diabetes is contested by some, who say that if retinitis is met in diabetic patients it is due to the presence of albumin accompanying sugar in the urine.

Nothing is less exact, says Prof. Dieulafoy, as albumin is by no means a proof of Bright's disease, and also retinitis can be observed in diabetes, of which the urine is free from albumin. All the portions of the eye are touched in diabetes: the external muscles (paralysis), internal, with troubles of accommodation, crystalline with cataract, vitreous body with hæmorrhage, retinitis with hæmorrhage and white spots.

Diabetic retinitis exists independently of Bright's disease, and is essentially different from that of this affection, where the white spots are larger and more abundant, and form a fan around the macula, while in diabetes these spots are punctated, and form a circle around the macula.

A woman of 60 years of age complained of thick cloud suddenly covering the vision. Examination showed disseminated hæmorrhagic spots on the retina, as well as whitish exudation around the macula. She suffered also from thirst and vulvalar pruritus; a considerable quantity of sugar was found in the urine, and no albumin. Under the effect of treatment, the sugar diminished notably, and the condition of the eye improved.

Another patient, besides ocular trouble, had a recrudescence of his diabetes under the influence of milk diet. The symptoms and signs of retinitis were similar to the preceding case, and albumin was present in the urine, as well as sugar. Under the effect of antipyrin and the suppression of the milk diet, which is not suitable for every case of diabetes, the sugar disappeared, but the albumin persisted.

In reality, albumin is found in more or less quantity in the urine of most diabetic patients, but it does not follow that the cause should be ascribed to Bright's disease. The cause is rather explained by the existence of bulbar irritation of gouty or arthritic origin, which produces both sugar and albumin. An intelligent antidiabetic treatment is capable of effecting a cure.

Broncho-Pneumonia.

In treating broncho-pneumonia, no time must be lost in employing energetic measures, and notably the wet pack. A towel is steeped in cold water, applied around the thorax, and covered with impermeable tissue. The application is removed at the end of two or three hours, when it is renewed after a smart rubbing of the chest. Warm baths succeed better than cold baths, especially when the heart shows signs of weakening. The patient is put into a bath of 100°, and the temperature gradually increased to 104°. The bath may be renewed twice in the 24 hours.

These means considerably abridge the duration of the malady.

The mustard bath might be utilised as an energetic revulsive, but a method which literally, says M. Hirtz, has brought back to life patients considered as absolutely lost, consists in placing the patient in a half bath of warm water and pouring over his body cold water (64°).

Internally, stimulant agents find their indication :—

Syrup of tolu, 4 oz.
Brandy, 1 oz.
Acetate of ammonium, 1 dr.
Water, 4 oz.

Every two hours a tablespoonful. No drugs that would lower the temperature should be given.

GERMANY.

Berlin, June 7th, 1908.

At the Medizinische Gesellschaft, Hr. Plehn showed a case of

Pernicious Anæmia.

The patient was a young man who was admitted into hospital in a very much reduced condition, so much so that his death was expected every hour. Suddenly, improvement set in, with rapid increase in the blood corpuscles and increase of body weight, so that in the course of six weeks he gained 32 lbs. The hæmoglobin increased to 60 per cent. The treatment had consisted in washing out the stomach and subcutaneous injections of arsenic. Notwithstanding the rapid increase in the red blood corpuscles, those containing nuclei had not increased. Notwithstanding the present good condition of the patient, the prognosis was still very doubtful.

Hr. Senator observed that the hæmoglobin was the last to re-establish itself.

Hr. Ewald brought to mind other observations of rapid improvement, which did not, however, exclude relapses.

Hr. Joseph showed a child, æt. 8, who had a nodule at the umbilicus which was at first taken for a hernia until suppuration appeared in it. In the Koenig. Poliklinik the pus was aspirated, when it appeared that the fluid aspirated was urine. A catheter introduced through the fistula showed in the bladder. The speaker now opened up the fistula, which led, first of all, into an abscess cavity; this could not be excised, as it was too firmly adherent. He then contented himself with tamponade, when the flow of urine became less.

The Keating-Hart Fulguration Treatment of Cancer

was then discussed. Hr. Max Cohn thought the treatment suitable for inoperable cases. He made flap incisions in the skin so that the sparks could act on the uncovered tumour. The action was entirely mechanical. Hr. Abel showed an improved apparatus for applying the treatment, which admitted of accurate dosage. Deep narcosis was necessary for the applications. They lasted a long time, and they were by no means indifferent to the suffering patient. The action of the sparks was only superficial. There was no bactericide action, for when cultures were exposed to its influence the growth of the organisms was not influenced in the least. No opinion as to the value of the method could be given at present. The subject was also discussed at the German Society for Surgery. Hr. Czerny, Heidelberg, said the current no doubt destroyed cancer cells and connective tissue, but the final results were not yet known. There was no question of permanent healing. The lightning did not destroy carcinomatous tissues completely. The distant action was but slight. The treatment was exceedingly painful. Hr. Sonnenburg said the *technique* was extraordinarily troublesome, but the method was strictly scientific, and well deserving of attention. Schultze, Berlin, did not believe in an elective action of the current; it burnt and destroyed everything alike.

Hr. Kocher, Berne, spoke on

The Technique of Transplantation of the Thyroid.

He rejected the direct transplantation of the thyroid into the marrow of bones. The hyperplastic gland substance was eminently adapted for transplantation. The vascular supply should be taken care of up to the moment of transplantation. For a covering only the firm periosteum was made use of. He took freshened tissues, and only removed the capsular parts when the piece had been placed in the cavity made in the tibia. The advantages of the operation lay in the lesser danger and risk. Hr. Payr, Greifswald, said that in his own case the result was by no means an ideal one. Hr. Garré, Bonn, in a case of chronic tetanus had transplanted epithelial corpuscles from a case of Basedow's disease into the epiphysis. There was a marked improvement after two months. The capsule of the epithelial corpuscles must be allowed to remain.

Hr. Czerny transplanted the thyroid into the spleen. Death followed from pneumonia. The thyroid was found properly healed in within the spleen. Hr. Müller, Rostock, had had bad results, as had also Moskowicz, of Vienna.

AUSTRIA.

Vienna, June 7th, 1908.

Bony Defect in Head.

Latzko showed an infant to the Gesellschaft with a defect in the left parietal bone from prolonged pressure *in utero* owing to a narrow deformed pelvis. In this case it was important to get a live child, and the conjugata vera being no more than 8 centimetres, or 3 inches, grave doubts were entertained of success. The mother had been 22 hours in labour, with a temperature of 37.5 Centigrade, it was clear something must be done, as delivery by the natural channel was scarcely possible. Then arose the question of operation, which should be adopted, symphysiotomy, hebostotomy, or the Cæsarean section. He decided on the latter, with Frank's modification of supra-symphysarial liberation. By this method Frank maintained that he could prevent infection of the peritoneum in the Cæsarean section by making a free opening in the uterine cavity below the peritoneal sac. The great secret of his operation was in a transverse section of the peritoneal membrane; he formulated the mode of performing the operation by first raising the pelvis, making a transverse section of the skin and muscles two or three ctms. above the symphysis; next, entering the peritoneum transversely over the bladder, and raising the loosened peritoneum above the lower uterine segment, and sewing both anterior and posterior walls of the sac to prevent any infection rising higher in the abdomen; after this the uterus was entered transversely at the lower segment, the child removed, drainage provided for, and the uterus closed, while the abdominal wall was left partially or completely open. Latzko thought these directions too complicated and sought to enter externally by a long incision along the linea alba till he reached the peritoneum, after which he cut the latter transversely. To assist in guiding the operation he injected 150 ctmcs. into the bladder, then moved the organ by means of a spatula from the cervix of the uterus carrying the loose serous membrane upwards. After this he opened the uterus in the direction of its fibres, removing fœtus and placenta, and then closed the wound in the usual way. Herzfeld thought that the Cæsarean section was an operation in favour of the child and regardless of the mother, and therefore questioned the righteousness of such an operation unless the circumstances were extreme. The great end to be obtained in parturition was asepsis and perfect drainage. Where the channel was narrow, as in the case recorded, craniotomy was still left as an ultimum refugium before the Cæsarean section was reached. He considered the latter too serious a danger to the mother, and thought Frank's operation should always be avoided. The peritoneal cavity is easily infected from the genital canal, and the loose cellular tissue around, no matter how ingenious the operation. Schauta agreed with the preceding speaker that the first consideration in cases of the kind was the safety of the mother. The Cæsarean section was always a momentous operation.

He thought pubiotomy or hebostotomy would have been quite sufficient in this case, and the risks far less. For the simple reason of obtaining a live child the Cæsarean section should never be undertaken. He had never practised Frank's method, nor could he see that lessened the danger of infection, because the vascularity was even greater where he recommended the operation, and the removal of the child was certainly more difficult owing to the depth in the pelvis, where the incision was made in the uterus. Latzko's extra-peritoneal sectio Cæsarea can hardly be called sectio Cæsarea vaginalis, as the vagina is never reached—the cervix being the lowest point. Even though the vagina were reached, hebostotomy is a superior operation, as the pelvic tissue is well known to be more susceptible to poisons than other parts of the body, and with his section the discharge of the uterus must still pass over the wound. Again, cicatrices would make future parturition still more dangerous.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Edinburgh Medical Faculty.—With the resignation of Professor Crum Brown two chairs are now vacant in the Faculty of Medicine. The chair of chemistry is under the patronage of the Curators, and applications are requested to be sent into the Secretary, Mr. R. Herbert Johnstone, W.S., on or before the 4th of July next. There is a considerable feeling of disappointment, if not of dissatisfaction, at the long delay in filling up the chair of clinical surgery, which has now been empty since the beginning of the year. Whoever be nominated, there must in consequence be a considerable re-shuffling of junior surgical appointments, and the holders of such as may be influenced in this way are naturally perturbed by the delay. Presumably, however, the new Professor will be nominated in time to take over his duties at the beginning of next October.

BELFAST.

Death of Dr. Sydney Brice Smyth.—The tragically sudden death of Dr. Sydney Brice Smyth on Thursday last has cast a great gloom over the medical profession in Belfast, where he was a universal favourite. To the general public he had seemed in the best of health and spirits, though his intimate friends knew that he had latterly had frequent signs of asthma and easily became cyanosed. He was making arrangements for a holiday in Sweden in a few weeks 'time, and no special anxiety was felt for him; but on the morning of the 4th inst. he was found dead in bed, having evidently passed quietly away in his sleep. The deepest sympathy is felt with his relatives, and specially with his father and two brothers, all medical men. His father, Dr. Brice Smyth is a senior member of the profession in Belfast, and after enjoying one of the best general practices in Ulster for many years he was gradually lessening work as his eldest son took more in hand. The three sons were educated at Uppingham School and Trinity College, Dublin. Dr. Sydney Brice Smyth began practice in Belfast about fifteen years ago, and devoted himself specially to obstetrics and diseases of children. He was appointed to the staff of the Belfast Children's Hospital, and later to the Maternity Hospital. He devoted a great amount of time and trouble to his work at the Children's Hospital, and was rewarded by attaining a high place in his profession, for though only 39, he had become a recognised authority in the treatment of children, and was frequently called out in consultation by his colleagues. He had also a large and valuable midwifery practice. He used to be an ardent cricketer, but lately had become very stout, and took almost no exercise, except yachting on Saturdays during the summer months. His kindness and good nature were proverbial, and among a wide circle of friends and patients he was not merely liked, but loved. He was a bachelor, and spent much of his spare time with his father and youngest brother, Dr. Malcolm Brice Smyth, who is also in practice in Belfast. His other brother, Dr. R. Brice Smyth is deputy medical superintendent at the County Asylum, Gloucester. The funeral, which took place on Saturday morning, was strictly private.

LETTERS TO THE EDITOR.

THE STATUS OF PRISON MEDICAL OFFICERS IN IRELAND.

To the Editor of The Medical Press and Circular.

Sir,—I was much interested in your editorial *re* Prison Medical Officers in your issue of the 3rd inst., Irish Poor-law and Lunacy Intelligence.

The question is a very simple one, and the mere statement of facts will show what an injustice the medical officers appointed to prisons since the passing of the Prisons (Ireland) Act, 1877, suffer from. By the Act of 1873, the position of gaol surgeons as regards pensions was definitely settled. They were placed in the same position as civil servants. On completing their service, and reaching the age of 60, or, in case of illness, prior to that age, they were entitled to one-sixtieth of their salary for each year's service completed, the maximum pension obtainable being two-thirds of their salary. There was this important distinction from civil servants—they were not called on to resign when the age of 60 was reached. Under a clause in the Prisons Act, gaol surgeons in future were to be appointed by the Lord-Lieutenant. The wording of the section is somewhat intricate, but the Government have acted on the assumption that the Lord-Lieutenant has power to determine the tenure of office. By making the appointment of gaol surgeons for a period of three years (renewable at the discretion of the Lord-Lieutenant), the office of gaol surgeon ceases to be pensionable. Several questions arise:—

(1) Have the Government interpreted aright the section of the Prisons Act empowering them to override the Act of George, whereby these officers were secured in their tenure for life? The House of Commons never intended that any alteration in status should be made. In the case of prison medical officers, who also held the appointment of county infirmary surgeons, a special clause was inserted to clear up an ambiguity as regards *their* pensions.

(2) A much more important question than that of pensions is raised by allowing the tenure of medical officers to prisons, viz., the independence of the medical officers—they are placed in a position of extreme responsibility—their business is to maintain the health of the prisoners while not interfering with the general discipline of the prison. They are the only safeguard vouchsafed to the prisoner, to prevent rigorous confinement on a scanty diet, causing a deterioration in health or *morale*. Without independence, vexatious interference by a controlling power is possible, and not only possible, but certain to take place. If a Royal Commission on Prisons in Ireland was appointed, similar to that of 1884, I think numerous instances would be forthcoming. If for no other reason, the alteration in tenure of prison medical officers, is a retrograde step fraught with danger to the prison population—when a class is deprived, though it be through their own acts, of medical attendants of their own selection, it is doubly imperative on the Government that their medical attendant, for the time being, should be placed in a condition of perfect freedom from restraint or interference. I write with 31 years' experience as a prison medical officer, but, happily, as a permanent pensionable officer, doubtless one of the two referred to by the Attorney-General.

The Attorney-General's statement that only those medical officers whose whole time is given to these offices, are entitled to pension, is perfectly true; but why? Because the Government have altered their tenure of office; if they were permanent officers the Act of 1873 made them pensionable. The House of Commons legislated for medical officers whose whole time was not given to the Service; mine is a case in point. There are ex-medical officers now, who are drawing pension, whose whole time was not given to the Service. If, instead of the Treasury attaining this paltry saving in pensions, the Government had gone to the House of Commons and attempted to alter the tenure of medical officers by legislation, they would have been defeated. The House of Commons has not altered its opinions since 1873, when they specifically granted medical officers, whose whole time was not given to the Service, pensions. Had they proposed this the entire strength of the Irish M.P.s would have been cast against them, together with those English and Scotch M.P.'s whose sense of fairness and sympathy is not alienated by party discipline.

While the emoluments of the office are utterly disproportionate to its importance, it is grossly unfair to the profession at large that any of its members should be deprived (by a side wind) of privileges Parliament granted them in 1873, and intended them to enjoy till such time as in their wisdom it saw fit to repeal.

There is much more that I could write on this subject, but my position precludes me from entering into details in support of my contention. I only, therefore, deal with the broad constitutional question, and must express my regret that the subject does not present itself to M.P.'s (especially Irish M.P.'s) with the importance it deserves.

I am, Sir, yours truly,
Hercules MacDonnell, M.D.,
Medical Officer H.M. Prison, Dundalk.

THE GOVERNMENT COMMISSION ON WHISKY.

To the Editor of The Medical Press and Circular.

Sir,—Incidentally to the Whisky Commission, much has been talked and written on the subject of "What is Whisky?" May I, as a member of the trade who, with forty years' experience in the tasting and sale of whiskies, am, rightly or wrongly, regarded as an expert, state a few simple facts (abstaining from all trade technicalities), and give the result of my experience, which may be of some interest to your readers.

The public taste and the demand for Irish whisky, which, in certain well-known brands, claims to be "all malt," has for many years declined, whereas during the same period the trade and demand for blended Scotch whiskies has, both in this country and abroad, enormously increased, and this only since the introduction of the skilful Scotch blends of malt and grain of good quality, which blends have made the reputation of Scotch whisky.

Distributors like my firm (who are neither distillers nor blenders) obtain practically the same rate of profit on the sale of *all malt* as on *blends*, and therefore hold no brief for either; but as a taster and merchant who during a lengthened period of years has sold considerable quantities of both, I unhesitatingly state that "all malt" does not suit the public taste, a fact which, apart from every-day business experience, I have verified specifically at three different periods: the first about the year 1892, the second in 1898, and the third in 1905, when on each occasion I purchased appreciable quantities of the finest and oldest pure malt that money could purchase, and had such bottled, sold and distributed at a moderate price amongst a large number of purchasers. Few repeat orders were received for this undoubted pure old malt of best quality, which was not appreciated, whereas during the same period repeat orders and evidence of appreciation were received daily for best blends of malt and grain. "All malt" is almost invariably found "heavy, heady and bilious," whereas blends of good malt and grain, well aged, are more appreciated.

In my opinion, the great desideratum is a skilful blend of good quality malt and old grain, both aged in cask for at least three years before blending.

The Whisky Commission can do some good by recommending that whisky should not go into sale for consumption before having been kept in bond for at least three years, a step which the medical profession has all along insisted on. This would inflict no hardship on "the trade," as blends of good whisky of an age up to twenty years can be and are sold to the public at as low a price as 39s. per dozen.

I am, Sir, yours truly,
F. B. Ehrmann.
Finsbury Square, London, E.C.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Three Cases of Acute Appendicitis.—The first case operated on by Mr. Corner was that of a little girl, æt. 9, who had been ill with abdominal pain, sickness, and inaction of the bowels for 48 hours. She presented all the clinical features of acute abdominal trouble. At her age, Mr. Corner said, such a condition was far and away most likely to be due to appendicitis; other causes being such uncommon events as obstruction by, or inflammation of, Meckel's diverticulum. An examination of the child showed absolutely no feature that she was suffering from disease of the appendix—the diagnosis being in consequence made on probability gained by previous experience. There were two or three clinical peculiarities about her case: the pulse was rapid, 130 to 140, out of all proportion to the signs of disease found by abdominal examination. In such cases it must be remembered that the disease causing the rapidity of pulse and the other serious constitutional signs was in all probability situated in the pelvis, where its presence need not be obvious on abdominal examination. Peritonitis when in the pelvis was particularly liable to affect the peritoneum over the small intestines, in which case it spreads rapidly over an enormous area producing severe constitutional symptoms in a very short time. Under such circumstances it was of the greatest importance when considering the question of surgical interference to ascertain whether the infection is spreading, perhaps insidiously, *viâ* the pelvis. A rectal examination which should never be omitted in acute abdominal conditions had been made in this case, and confirmed his conjecture that in her case the peritonitis had involved, and was spreading rapidly over, the small intestines and the pelvis. Under these circumstances operation would be undertaken without delay. The incision used to open the abdomen in such cases was best made over the right rectus muscle, the fibres of which are separated; the peritoneum can be opened, if necessary, from the ribs to the pubes, and the whole abdomen explored. Little free fluid was present in the peritoneal cavity, though previous to the operation its presence had been suspected, the confusion arising from the inability of the clinical examination to distinguish between fluid free in the peritoneal cavity and fluid within the coils of the bowel. The appendix was situated near the brim of the pelvis, and was gangrenous. The infection from it on account of its situation affecting the small bowel in the pelvis and lower part of the abdomen rather than the contents of the abdomen proper. The pelvis and lower part of the peritoneal cavity were carefully sponged out with long gauze plugs. The appendix was removed. There were two points of value, Mr. Corner remarked, in the prognosis which were indicated before the abdomen was closed: in the first place the patient was a child where the prognosis is far more uncertain than it is in young adults; in the second place it was noted that the intestines were red and dilated, but they showed no lymph or other traces of reaction on the part of the body against the infection. The wound was partially closed, gauze drains being left leading to the pelvis and to the lower part of right iliac fossa to be removed in forty-eight hours.

The child had a stormy convalescence, but ultimately recovered.

The other two cases:

1. Acute appendicitis mimicking acute cholecystitis in a woman, æt. 40;
2. Very acute early appendicitis in which the diagnosis could not be confirmed until the appendix had been removed and opened,

will be published in "Operating Theatres" in a future number.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Pneumonia Due to Friedlander's Bacillus.—Apelt, as a result of his research work, has come to the conclusion (*Munch. Med. Woch*, 1908, No. 16), that there are undoubtedly cases of pneumonia brought about by the diplo-bacillus of Friedlander. The bacillus can be found in the blood, the sputum, and ultimately, in fatal cases, in the lungs. This form of pneumonia is characterised by an absence of herpes and rigor, by a very severe onset, by a strongly mucoid expectoration, caused, apparently entirely by the pneumo-bacillus, and by the peculiar bright red appearance of the lung on section. Throughout the section, in addition, small mucoid areas can be detached. The treatment is the same as for pneumonia caused by the pneumococcus. M.

Adenoid Vegetations Among the Japanese.—Dr. Sakai has contributed to the February and March numbers of the *Sei-I-Kwai Medical Journal* a report of his study of adenoid vegetations amongst the Japanese, and has devoted special attention to the changes in the upper jaw brought about by their presence. He presents the following conclusions:—(1) The disease is most frequent between 6 and 15 years of age, and is met with equally in the sexes. (2) The symptoms most often complained of are occlusion of the nasal cavity, or deafness. (3) The changes found in the upper jaw are of two varieties, and are entirely due to the nasal obstruction. The first variety is found when the adenoids start before the period of true dentition, and is characterised by an increase in the long diameter of the superior maxilla, by the bright and semi-circular curve of the palatine arch, and by the absence of irregularity of teeth. The second variety presents a pointed palatine arch, and teeth irregularity. It is met with when the adenoids occur during the period of dentition. No deformity results if the vegetations appear after the period of dentition. (4) The lower jaw and the milk teeth never present any change. M.

The Cardio-Hepatic Angle.—Calvert presents a brief, but interesting, study of the cardio-hepatic angle in the *Johns Hopkins Hospital Bulletin* (May, 1908, p. 143). Ebstein, following Rotch, gave this name to the angle formed by the right border of the cardiac dulness and the upper border of liver dulness, and Rotch insists that dulness extending in this region beyond the right border of the sternum in the fifth intercostal space is an early and important sign of pericardial effusion. According to the present writer, the following two factors are necessary to materially alter this angle, viz.: (1) Displacement of the root of the lung; either to the right; to the right and upwards; to the right, upward and backward; or backward and upward. (2) Displacement of the lower portion of the right wall of the pericardium, either by an effusion or by very great dilatation of the right auricle. In pericarditis three factors are present to cause the dislocation of the lung, and these are:—(1) Possible displacement of the root of the lung. (2) Pressure of pericardium on lung from root to lower border. (3) Downward displacement of the attachment of the right wall of the pericardium to the diaphragm, thereby lowering the point of greatest displacement of the right wall of the pericardium. These factors are usually absent in cases of enlargement of the heart, in which the lung displacement is likely to be purely local, and in consequence Rotch's sign is of great value in diagnosing pericarditis. It is only in late stages of mitral stenosis that any real confusion is likely to occur. M.

Tumour of the Pituitary Body in a Young Boy.—Eiselsberg and Frankl. Hochwart describe a case of a young boy, æt. 12, who came under observation with characteristic symptoms of a tumour of the pituitary body (*Neurolog. Centralbl.*, 1907, No. 21). The fact that typical acromegalic symptoms were absent and that there were no congestive phenomena, while there was rapid deposition of fat, accompanied by the appearance of symptoms resembling myxœdema, led to the conclusion that the gland itself was the site of tumour formation. X-ray examination also assisted the diagnosis. An operation was undertaken for the purpose of improving the vision, and relieving headache, the tumour being approached through the frontal sinus to the sphenoidal sinus, and a cyst of the pituitary body was found. This was cleared out of a mass of broken-down tumour and blood *débris*, epithelial cells being found in numbers in what was removed. The patient completely recovered, and, except for some loss of olfactory sense, has remained in good health. M.

Coagulation of the Blood.—Robertson, Illman, and Duncan (*Journal of the American Medical Association*, May 16th, 1908) publish a summary of our knowledge of the process of coagulation with special reference to the action of alleged coagulation. The following are the more important conclusions:—(1) During the febrile stage of the infectious diseases coagulation is noticeably retarded. (2) The administration of calcium salts had no invariable effect on the coagulability of the blood. (3) No definite relation could be established between leucocytosis and coagulation time. (4) Citric acid prolonged the coagulation time and diminished the viscosity of the blood. R.

The Testicle and Typhoid Fever.—Fox (*Bulletin of the Ayett Clinical Laboratory of the Pennsylvania Hospital*, December, 1907) discusses the occurrence of focal necroses in the testicle in the course of typhoid fever. For some time it has been known that focal necroses are a marked feature of the pathology of typhoid fever. First discovered in the liver, they were afterwards found in the spleen, in mesenteric lymph-glands, and in bone-marrow. Fox studied the testicles from 26 cases of typhoid fever, from 17 cases of pneumonia, and from 9 miscellaneous cases, including nephritis, peritonitis, purpura hæmorrhagica, myocarditis, and carcinoma of the stomach. There were two striking features noticed in the testicles from cases of typhoid fever: the large number of epithelioid cells in the tissues between the tubules, and the almost complete absence of spermatogenesis. In the testicles from pneumonia, on the other hand, spermatogenesis was active. In 12 of the 26 cases of typhoid, focal necroses were found in the testicles. As a rule, the foci were fairly large, but they varied greatly in number. The general features of the lesion were an area densely packed with small round cells and large epithelial cells, with a very few polymorphonuclear cells. The centre of the area was necrotic, and about the border of the necrotic portion there was nuclear fragmentation and granular detritus. Hæmorrhages were also common in the glands. In one case of pneumonia there was a focus of necrosis in the epididymis, but in none of the others, nor in any of the miscellaneous cases were any necroses discovered. Fox discusses the various theories as to the cause of focal necroses in typhoid fever, and inclines to the view that a bacterial toxin is the direct cause of the lesions. There was no thrombosis or vascular change sufficient to account for them, and there was no evidence to suggest that they were due to the action of the bacilli on the cells themselves. The suggestion of Flexure is quoted with approval, that in capillaries in which the circulation is much diminished the toxic irritant may cause so much damage to the vessel-wall that free transudation of toxic fluid takes place into the tissues of the neighbourhood, resulting in destruction of the cells. R.

Pneumococcal Peritonitis.—Cuff (*Brit. Med. Journ.*, April 18th, 1908) collects five cases of primary pneumococcal peritonitis. His views support recent teachings regarding the wide distribution of the pneumococcus as a pathological agent in the body. He notices a peculiarity about the pus in cases of pneumococcal infection of serous membranes. There is always a large quantity of coagulated lymph like curdled milk. He concludes from his study of the five cases:—(1) An acute or localised peritonitis may be the sole symptom of a pneumococcic infection. (2) Such cases form a considerable proportion of those anomalous cases of peritonitis without visible lesion of any of the abdominal viscera. (3) They may be followed by pneumococcic lesions in other parts of the body. R.

A Case of Merycism.—The literature of merycism, or chewing the cud, as a human abnormality, is increasing. Taylor (*Brit. Med. Journ.*, March 14th, 1908) reports a case occurring in a native boy of 14 in the Punjab. He had been subject to the condition for some four years, the food beginning to return to his mouth immediately after a meal. It came up quite soft, and, without re-chewing, he again swallowed it. The action was quite automatic, and went on regularly till he began to feel hungry for the next meal. There was no family history of merycism, and the health of the boy was good. R.

Cancer of the Vermiform Appendix.—McWilliams (*American Journal of the Medical Sciences*, June, 1908) publishes a careful study of 90 cases of primary carcinoma of the appendix, while Kelly adds notes on a few cases which came under his observation. The following are the principal conclusions arrived at by McWilliams:—Of the patients operated upon for known reasons, 83 per cent. suffered from some variety of appendicitis. Eleven primary cancers were found in appendices removed in the course of operations undertaken for other purposes, and 10 primary cancers were found in the course of autopsies. In 60 per cent. of the cases the patients were under 30 years of age. The condition was somewhat more frequent in women than in men. In only 5 per cent. of the cases were there concretions in the appendix. The site of the growth was most commonly near the tip of the appendix. It was rare to find the lymph-glands involved. In many of the cases no tumour was observable to the naked eye. The type of cell differed in different cases—in 22 per cent. it was columnal, in 53 per cent. sphenoidal, in 9 per cent. transitional. The spread of the cancer is slow, the appendix being infiltrated through all its coats in only half the cases. In 22 pe cent. the meso-appendix was affected. There is little tendency to the formation of metastases, secondary growth being present in only 6 per cent. of the cases. In 62 per cent. there were chronic inflammatory changes in the appendix, but it was impossible to say whether they or the cancer were primary. R.

The Effect of Muscular Exercise ou Temperature.—Flack (*Brit. Med. Journ.*, April 18th, 1908) publishes observations on the rectal temperature of athletes taken immediately after severe muscular exercise. One set of observations was made on competitors in the London Hospital and Inter-Hospital Sports. The lowest record is 100° F., in the case of a man who had run one mile, and again when he had run nearly two miles. The other records varied from 100.2° F. to 105° F., the average being between 101° F. and 102° F. Speaking generally, the longer the effort the higher the temperature rose. The man whose temperature reached 105° F. was carefully observed and examined afterwards, and he was regarded as perfectly healthy. Another set of observations was made on players in the Inter-Hospital Rugby Final Match, with similar findings. The records varied from 101.2° F. to 103.40 F. R.

Rhabdo-myo-Sarcoma of the Prostate.—Greig (*Brit. Journ. of Children's Diseases*, May, 1908) reports a case of this rare condition occurring in a child of four years. The tumour was an irregular fungating growth, the size of a Tangerine orange, projecting into the bladder round the urethral orifice. It was quite friable. Microscopically it was found to be a sarcoma, possessing in parts a fair number of striped muscle fibres. The sarcoma cells were spindle-shaped, with marked variations in size. Greig has only been able to find a record of three other cases of the condition, all of them reported by Socin and Burckhardt. R.

Alcohol and Protoplasm.—Kesteven (*Brit. Med. Journ.*, April 18th, 1908) records some interesting experiments as to the effect of supplying live amœbæ with alcoholic solutions. Several different specimens of amœbæ were employed, and various strengths of alcohol from 1 to 7 per cent. in water. In the weaker solutions the amœbæ at once became motionless, but after a varying time, from seven minutes upwards, motility was again apparent. In the stronger solutions the amœbæ were at once killed. The observer concludes that, though the animals could live in solutions not exceeding 5 per cent. of alcohol, the effect in every case was one of paralysis, only differing in degree. There was no sign of any stimulating effect. R.

MEDICAL NEWS IN BRIEF

Proposed New Irish Universities.

The following have been nominated as Commissioners to discharge the duties of Commissioners under the Irish Universities Bill. For the Belfast Commission:—The President of Queen's College, Belfast, His Honour Judge Shaw, Professor Symington, Professor Dill. In addition, Mr. Birrell hopes to secure two gentlemen of great academic authority, experienced in University matters in Great Britain, and possibly a seventh person will be nominated.

For the Dublin Commission:—The Presidents of the three Colleges, the Most Rev. Dr. Walsh, Roman Catholic Archbishop of Dublin, the Lord Chief Baron, Sir John Rhys, Dr. Henry Jackson, Regius Professor of Greek in the University of Cambridge, the hon. member for Galway (Mr. Gwynn). The hon. member for Cambridge University (Mr. Butcher), whose assistance was hoped for, is unable to undertake the duties. One or more additional members will probably be asked to serve.

Royal College of Surgeons.—Annual Election to the Council.

The forthcoming election to the council of the Royal College of Surgeons will take place at the college between the hours of three and five on July 2nd. The retiring members of coucil this year are Mr. Pearce Gould, Mr. Ward Cousins, and Mr. W. Harrison Cripps. Mr. F. Howard Marsh has also resigned his seat on the council. There will thus be four vacancies to be filled. It is understood that Mr. J. Ward Cousins will not offer himself for re-election. The following is the final and full list of candidates:—Mr. Pearce Gould and Mr. Harrison Cripps (who offer themselves for re-election), Mr. George Eastes, Mr. W. Arbuthnot Lane, Mr. Bilton Pollard, Mr. C. B. Lockwood, Mr. G. F. Haslam (Birmingham), and Mr. J. Lynn Thomas (Cardiff). Voting papers will be sent by post to all Fellows of the College on the 19th instant, whose addresses in the United Kingdom are registered at the college, and Fellows are not required to apply for them.

Northampton Consumptive Sanatorium.

The well-known Northampton firm of Messrs. C. and E. Lewis have already subscribed over £400 towards the Building Fund of the County Consumptive Sanatorium, and now they promise a further £300 upon the following conditions:—£100 provided four similar sums are collected, a further £100 on the same conditions; £50 provided that four more £50 are subscribed; and another £50 on the same conditions.

This announcement was made by Mr. James Lewis at the monthly meeting of the Sanatorium Committee on Thursday, and the offer was very gratefully accepted. There has been a great revival of interest in the scheme, and Messrs. Lewis feel that in order to secure a large measure of support building operations should be commenced as soon as possible. Up to the present about £3,100 has been raised, and that another £3,000 is required before the work in all probability is commenced, because the committee does not wish the institution to be saddled with a mortgage.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Disco.—We cannot undertake to reply to communications unless verified by name and address.

O. E. CLUB TRIENNIAL DINNER AT EPSOM.

To the Editor of The Medical Press and Circular.

Sir,—According to the minute made at the Annual Meeting, December, 1907, it has been arranged to hold the Triennial Dinner of the Club at Epsom College, on Tuesday, July 7th. The cricket match against Surrey Club and Ground will be in progress. The Head-master and Mrs. Smith Pearce have asked us to tea, about 4.30. The Council will entertain us to dinner at 7 p.m. Chapel is at 8.45. There are trains back to Waterloo at 9.36, and to Victoria and London Bridge at 9.25.

Owing to the accommodation, the number of those dining must be limited to 50. All members intending to dine must send me notice before *Thursday, June 25th*. If the number of those desirous of dining exceeds 50, a ballot must be held; in which case, notice of the result will be sent to all who have signified their desire to come.

I am, Sir, yours truly,
Edred M. Corner,
Hon. Sec.

37, Harley Street, W.

K. (College of Surgeons).—A private letter has been sent to you.

Meetings of the Societies, Lectures, &c.

Wednesday, June 10th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. L. Mummery: Clinique (Surgical). 5.15 p.m.: Lecture:—Dr. H. French: Points in connection with Intercurrent Medical Illnesses during Pregnancy.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2.30 p.m.: Medical Out-patient: Dr. Whipham. Skin: Dr. Meachen. Eye: Mr. Brooks.

Thursday, June 11th.

Royal Society of Medicine (Obstetrical and Gynæcological Section) (20, Hanover Square, W.).—7.45 p.m.: Specimens:—Mr. J. D. Malcolm: (1) A Uterus with Cancer of the Cervix removed by Wertheim's method; (2) A Cystic Ovary and Hydro-salpinx removed from a woman, æt. 58. Dr. T. W. Eden: A Case of Bilateral Papillary Carcinoma of the Ovary. Dr. Cuthbert Lockyer: (1) Sarcoma of the Uterus; (2) Tubal Gestation with Unusual Pathological Features. Dr. F. McCann: (1) Grape-like Sarcoma of the Cervix; (2) Bilateral Tuberculous Salpingitis. Short Communications:—Dr. Kedarnath Das: Gastroschisis. Papers:—Dr. J. H. Teacher: The Embedding and Development of a very Young Human Ovum. Dr. J. W. Munro-Kerr: Clinical History and Microscopical Description of an Early Ovarian Pregnancy.

Ophthalmological Society of the United Kingdom (11, Chandos Street, Cavendish Square, W.).—8 p.m.: Mr. Lawford, Mr. Winfield-Roll, and others: Card Cases. 8.30 p.m.: Mr. P. E. H Adams: An Epidemic of Contagious Conjunctivitis due to the Pneumococcus. Mr. E. Nettleship: (1) Senile Cataract in Husband and Wife, Condition of Lenses in Children and Grandchildren; (2) Lamellar Cataract, Discoid ("Coppock") Cataract and Retinitis Pigmentosa in the same Family; (3) A Colour-blind Family. Lieut-Col. H. Herbert: (1) Lower Corneal Plaques; (2) A Factor in the Production of Parenchymatous Xerosis.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.:—Mr. Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture:—Prof. T. Hewlett: The Diagnosis of Syphilis, etc., by the Antigen Method.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Special Demonstration of Gynæcological Operations: Dr. Giles. Clinics:—Medical Out-patient: Dr. Whiting. Surgical: Mr. Carson. X-Rays. 3 p.m.: Medical In-patient: Dr. Chappel. 4.30 p.m.: Throat Operations: Mr Carson.

Friday, June 12th.

Royal Society of Medicine (Laryngological Section) (20, Hanover Square, W.).—5 p.m. Cases and Specimens:—Dr. Watson Williams: (1) A Case of Malignant Growth of the Septum and Naso-pharynx removed by an External Osteoplastic Operation; (2) A Case of Laryngeal Disease for Diagnosis; (3) Skiagrams of the Accessory Sinuses. Dr. Herbert Tilley: (1) Specimen of a Large Post-Nasal Polypus removed from a boy, æt. 14; (2) Spectroscope Slide showing well-marked development of the Orbito-ethmoidal cells; (3) A Case of Subglottic Hyperplasia with considerable Narrowing of the Tracheal Air-way. Mr. Clayton Fox: A Case of Paralysis of the Right Vocal Cord in a Man with Myopathia. Mr. S. V. Cargill, Mr. William Turner, Dr. St. Clair Thomson: Orbital Cellulitis, Abscess of Left Frontal Cerebral Lobe, consequent on Acute Left Frontal Sinusitis; Operation; Cure. Dr. St. Clair Thomson: (1) Radiographs of the Sphenoidal Sinus; (2) Cases of Submucous Resection of the Nasal Septum. Mr. Stuart-Low: A Case after Operation for Angina Ludovici. Dr. Dan McKenzie: A Case of Malignant Disease of the Larynx. Dr. Jobson Horne: Preparations demonstrating the Exhibitor's Explanation of the Characteristic Appearances of Pachydermia Laryngis.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.:—Mr. R. Lake: Clinique (Ear).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic:—Surgical Out-patient: Mr. J. H. Evans. 2.30 p.m.: Surgical Operations: Mr. Edmunds. Clinics:—Medical Out-patient: Dr. Auld; Eye: Mr. Brooks. 3 p.m.: Medical In-patient: Dr. R. M. Leslie.

Vacancies.

Borough of Crewe.—Medical Officer of Health. Salary £230 per annum. Applications to Frederick Cooke, Town Clerk, Municipal Offices, Crewe.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £175 per annum, with furnished quarters, attendance, coal, gas, garden produce, milk, and washing. Applications to the Medical Superintendent.

City of Chester.—Assistant Medical Officer of Health. Salary £250 per annum. Applications to J. H. Dickson, Town Clerk, Town Hall, Chester.

Bucks County Lunatic Asylum.—Senior Assistant Medical Officer. Salary £175 per annum, with board and furnished apartments. Applications to Wm. Crouch, Clerk to the Visiting Committee, County Hall, Aylesbury

Lord Mayor Treloar Cripples' Home and College, Alton, Hants.—Resident Medical Officer. Salary £150 per annum. Applications to Sir William Treloar, 122-3 Mansion House Chambers, E.C.

County Borough of Salford.—Assistant Medical Officer. Salary £350 per annum. Applications to L. C. Evans, Town Clerk, Town Hall, Salford.

Appointments.

Campbell, Janet M., M.D., B.S.Lond., Member of the Medical Department of the Board of Education.

Farquharson, David A., M.B., F.F.P.S.Glasg., to the Chair of Physiology in the Royal (Dick) Veterinary College, Edinburgh.

Gardiner, Peter, M.D., C.M.Glasg., D.P.H.Lond., Medical Officer to the Camborne (Cornwall) Nursing Association.

Hawker, George Poole David, M.B., B.C.Cantab., Medical Officer to the Exeter Dispensary.

Jones, F. Emrys, L.M.S.S.A., Resident Pathologist at the Birmingham General Hospital.

Leighton, G. R., M.D.Edin., F.R.S.E., Professor of Pathology and Bacteriology at the Royal (Dick) Veterinary College, Edinburgh.

Ramsay, Jeffrey, M.B., B.S.Lond., Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

Stewart, A. H., M.B., M.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Queensbury District of the County of York.

Thomas, Josiah Telfer, L.R.C.P.Lond., M.R.C.S., Medical Officer to the Camborne (Cornwall) Nursing Association.

Walker, Cyril H., M.B.Cantab., F.R.C.S.Eng., Additional Lecturer on Ophthalmology in the Faculty of Medicine of University College, Bristol.

Wright, J. A., M.D.Cantab., Clinical Assistant to the Chelsea Hospital for Women.

Births.

Sandford.—On June 6th at 1, Collingwood Villas, Devonport, the wife of George C. Sandford, M.D., of a daughter.

Marriages.

Dobson—Anderson.—On June 4th, at St. Mary Abbotts, Kensington, William Greswell Dobson, ,Barrister-at-Law, eldest son of W. Dobson, of Plymouth, to Ella Kingdon, youngest daughter of Izett Anderson, M.D.Edin., of 22, Arundel Gardens, London.

Somerville—Ekin.—On June 6th, at St. Andrew's Church, Westminster, D. Gerald, only son of the late A. T. Somerville, Esq., F.R.C.S.E., Edinburgh, to Dora Wentworth, elder daughter of Mrs. Ekin, Brighton.

Deaths.

Nuttall.—On June 4th, at San Francisco, California, John Robert Kennedy Nuttall, eldest son of the late Robert Kennedy Nuttall, M.D., and brother of Professor George H. Falkiner Nuttall, F.R.S., aged 53.

MODERN THERAPY

MEDICAMENTA · VERA · P. D. & Co.

Hay Fever.

Clinical reports demonstrate that **ADRENALIN** is the most effective remedy in Hay Fever, ameliorating, almost immediately, the various distressing symptoms without undesirable sequelæ. Its powerful constringent action promptly reduces congestion, checks profuse secretion, and controls paroxysmal sneezing.

ADRENALIN CHLORIDE SOLUTION 1:1000.

This solution, diluted with 10 to 20 volumes of physiological sodium chloride solution (1 Compressed Tablet Sodium Chloride, P., D. & Co., No. 365, dissolved in 4 fl. ounces of recently-boiled distilled water), may be sprayed into the nostrils or applied on pledgets of cotton-wool to the septum and the accessible portions of the lower and middle turbinates, and also instilled into the eyes.

A writer in the *British Medical Journal*, 4th July, 1903, p. 60, states that relief was obtained by using this solution when the paroxysm threatened.

Supplied in bottles of 1 fluid ounce and 10 c.c., also in ampoules of 0.5 c.c.

ADRENALIN INHALANT.

This 1:1000 solution of Adrenalin Chloride in aromatised neutral oil containing 3 per cent. of Chloretone, secures more prolonged contact with the mucous membrane than does the aqueous solution. The antiseptic and analgesic properties of Chloretone are valuable auxiliaries. When thus exhibited, the action of the Adrenalin is so mild that dilution is not necessary. The Inhalant may be sprayed into the nostril and repeated in four hours if required.

A writer in the *Medical and Surgical Monitor* for January, 1905, records several cases of chronic hay fever successfully treated with Adrenalin Inhalant.

Supplied in bottles of 1 fluid ounce.

ADRENALIN OINTMENT, a combination of 1 part of Adrenalin Chloride in 1000 parts of a bland oleaginous base, is preferred by some medical men as it prolongs local ischæmia.

Supplied in collapsible tubes with elongated tips to facilitate nasal medication.

Prior to using either of these preparations, crusts of mucus should be removed from the nasal passages by a spray of warm alkaline solution such as may be obtained by diluting ALKATHYMOL (P., D. & Co.) with three volumes of warm water, or by dissolving one Compressed Tablet NASAL (P., D. & Co., No. 34) in four ounces of tepid water.

The "GLASEPTIC" NEBULISER is the most suitable appliance for administering Adrenalin Chloride Solution or Adrenalin Inhalant. Being free from metallic fittings danger of contamination is avoided, and having no vulcanite parts it may be readily sterilised by boiling.

Upon request we shall be pleased to send to any medical man a pamphlet descriptive of many of the almost innumerable therapeutic applications of Adrenalin.

PARKE, DAVIS & Co., LONDON.

Important Present Sale of 12,850 Dozen of an

UNIQUE OLD WHISKY

Of superb unsurpassed quality—great age and unequalled value.

ALEX. FERGUSON & CO.'S

"A distinct advance on Easton's Syrup."
—*The Lancet.*

"Bynin Amara"

'BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, therefore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

COMPOSITION.

Quinine Phosphate	1½ grains.
Iron Phosphate	2 ,,
Nux Vomica Alkaloids equal to Strychnine	$\frac{1}{16}$,,
'Bynin, Liquid Malt	1 ounce.

DOSE FOR ADULTS—One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

Antikamnia

ANALGESIC. ANTIPYRETIC. ANODYNE.

In the administration of Remedies to relieve PAIN, the element of exhilaration should be considered, as many produce such delightful sensations as to make them dangerous to use.

Such is not the case with Antikamnia Tablets.

They are simply pain relievers—not stimulants—not intoxicants. Their use is not followed by depression of the heart.

In cases of **Acute Neuralgia,** tested with a view of determining the analgesic properties of Antikamnia, it has been found to exceed any of its predecessors in rapidity and certainty of the relief given. **Neuralgia, Myalgia, Hemicrania,** and all forms of **Headache, Menstrual Pain,** &c., yield to its influence in a remarkably short time, and in no instance has any evil after-effect developed. The adult dose is one or two tablets every one, two, or three hours. To be repeated as indicated. All genuine tablets bear the AK monogram.

Strongly Recommended.

ANTIKAMNIA & HEROIN TABLETS

(5 gr. Antikamnia, 1.12 gr. Heroin Hydrochlor.)

A Respiratory Stimulant, Sedative, Expectorant and Analgesic.

Heroin Hydrochloride is indicated in Coughs of all kinds, in Dyspnœa, and in Catarrhal Inflammations of the Respiratory Mucous Membrane, and in all cases in which morphine is contra-indicated; while **Antikamnia** furnishes the Analgesic, Antipyretic, and Anodyne effect which is so soothing and comforting to patients.

ANTIKAMNIA Tablets
ANTIKAMNIA & HEROIN 5gr. Tablets } **Supplied in 1-oz. packages to the medical profession.**

NOTES AND COMMENTS.

Bag or Body?

THE man, "Bertram Mortimer," whose doings have already been commented on in these columns, and who has come to be known as the "Gold Dust" specialist, was convicted recently of stealing a Gladstone bag at Victoria Station, and sentenced to fifteen months' imprisonment in the second division. The fact that this crime was the only one pushed home is interesting, for he was committed for trial on two other counts of obtaining money by false pretences by posing as a medical specialist. The revelations made in evidence at the police courts, if they had been credited by a jury at the Assizes, would have established crimes of a far more cruel nature than that for which he was ultimately brought to book. To have a travelling bag stolen is an inconvenience, but to have the bodily health played with by a swindler is disaster of the first magnitude. Nevertheless, the Treasury carried the former crime to conviction, and apparently have dropped the others. The old-fashioned notion of the heinousness of crime against property is still very strong in legal circles.

Increased Sentence.

MORTIMER'S sentence produced an appeal under the New Act, and is notable for being the first case in which the Court adopted the plan of increasing the sentence awarded by the judge in the lower court. This very wholesome precedent is one that we hope will be largely followed, as it will deter scoundrels from trying to get off more lightly by appealing against their conviction, without impairing the value of the Court to wrongly-convicted persons. The Lord Chief Justice remarked that the prisoner had been sentenced in the first place to fifteen months' hard labour, but that this was subsequently reduced to fifteen months' imprisonment in the second division. Personally, he did not see why the sentence should be reduced, and Mr. Justice Phillimore remembering having tried Mortimer before, they agreed that the sentence should be altered back to fifteen months' hard labour. This incident served to illustrate the character of the men who go in for the quack business. They are protected in the lowest and meanest form of swindling by the anomalies of the law, which visits severe punishment on them when they commit such trivial crimes as stealing a bag, and they are supported by a considerable amount of public sympathy and not a little newspaper eloquence. To set up as a healer without having the necessary endowment in the shape of training is *primâ facie* evidence of swindling; it is more, it is definite evidence, for it is not possible for people so circumstanced to understand the nature of illness nor the efficacy of treatment in diseased conditions. The swindle is as great as if a man who knew nothing about electricity obtained money for promising to set up an installation.

Hospital Officers and Compensation Cases.

THE trouble we apprehended—not that a great amount of foresight was need for the prediction—in connection with medical evidence under the Workmen's Compensation Act is considerable, especially as regards hospital residents. With every desire to see justice done, and with every sympathy with injured workmen, we cannot but feel that it is not the duty of house surgeons and honorary medical officers who give their services to charitable institutions, to be called upon to absent themselves from their routine work to hang about county courts in these cases. Hospital work must go on, and there is always as much to be done as the officials can possibly do. Moreover, injured workmen, especially if their applications are unsuccessful, are not in a position to pay for expert medical evidence, and it is most unfair that medical men should be summoned to give evidence for inadequate fees or no fees at all, when their expert knowledge and their time is their stock-in-trade. The position is one that will have to be faced some time or another. At present the usual method adopted by solicitors is to summon the doctor as a common witness, and when he is in the box to ply him with expert questions. If a doctor is summoned as a common witness, he must attend, but if as an expert, of course he can demand his proper fee before doing so.

A Way They Have at the Bar.

A MOST disagreeable incident happened at the Shoreditch County Court the other day, and was reported in many of the daily papers. A medical man from an ophthalmic hospital was summoned to give evidence in an arbitration of a workmen's compensation case, and when called on to give evidence he informed the judge that he had been treated with very scant courtesy; that he had prepared a statement, but that if he was to be asked expert questions he was entitled to a fee before going into the box. Thereupon counsel, who was doubtless sure of his own remuneration, turned sharply upon him and informed the medical man that his attitude was scandalous, adding the unfair stroke, "The complaints continually made about hospital doctors by poor people appear to be well founded." The doctor thereat left the court, the judge not making any comment. Insult of this kind is intolerable. The more the medical profession does for nothing, the more is demanded from it. A way out of the difficulty must be found, and that way, as we have said before, is for the trades unions to employ their own medical officers and pay them adequately. Members of the unions could then get medical support in genuine cases, and the proportion of the fee they would pay would be inconsiderable.

Welsh Medical School. After all that has been going forward in the domain of Welsh education, especially as regards the University of Wales, it is not surprising that Cardiff is looking forward to the early establishment of a complete medical school in its midst. The recent visit of Professor Osler to the Infirmary of that town has stimulated interest in the project, and from what is being said it appears that only questions of ways and means stand in the way. When Cardiff was made a centre for scientific and intermediate medical studies, and the Welsh student arrested there before migrating to London hospitals, the spirit of national emulation was naturally roused. To this the only logical outcome was a demand for a fully equipped medical department. The necessary authority to grant medical degrees has been obtained, and doubtless we shall soon see the school in working order. The greatest practical difficulties at the moment is the necessary endowment for the more purely scientific chairs, the occupants of which could not practise their profession, but in so prosperous a place as South Wales, and with so many philanthropic Welshmen of large means this need not prove a grave hitch.

LEADING ARTICLES.

CAN THE LORD CHANCELLOR REFRAIN?

We make no apology for returning to the subject of Mr. Troutbeck and the recent inquest, to which we referred briefly last week, because now that the full facts are before the public, together with the comments of the people chiefly concerned, a state of things dangerous in the highest degree to the public interest is revealed. We will go further and say that a scandal pertaining to the administration of justice,—greater and more insidious than any we remember,—is suggested by these recent events. The facts may be briefly recalled. A lady living near Wandsworth Common had been for three years under the care of Dr. Biggs, one of the oldest practitioners in South-West London, a man universally admired, respected, and trusted by the public and his colleagues. As the symptoms in this lady's case developed, she was taken by Dr. Biggs to different leaders of the profession for consultation. Eventually, a diagnosis of cerebellar tumour was made, and the alternative of blindness and death, or of possible relief by a dangerous operation, placed faithfully before her and her relations. The latter course was decided upon, and after a searching clinical examination by Sir Victor Horsley, she was operated upon by him in one of the paying wards of the Bolingbroke Hospital. A tumour was found and scraped out, the false capsule and its attachments of course being left behind. Three days later, as so frequently happens in cerebellar disease, death occurred suddenly. The relatives, who felt nothing but gratitude to Sir Victor Horsley, Dr. Biggs, and the other medical men concerned, made their arrangements for the funeral, and a certain day was fixed. Suddenly like a thunderbolt came an order from Mr. Troutbeck for an inquest on that very day. Following this coroner's usual practice Dr. Biggs was not called, and Dr. Freyberger was put on to do the *post-mortem* and give evidence. Sir Victor Horsley protested at the inquest that the inquiry was perfectly unnecessary, Mr. Troutbeck replying that the public as represented by the coroner should be informed as to the cause of deaths following operations, and that he intended to inquire into such deaths. Dr. Freyberger made a gross blunder, asserting that he had found a tumour not removed by the operation—the tumour being merely blood-clot which had collected in the false capsule, and Mr. Troutbeck directed the jury to return a verdict, not of "Natural Death," as indicated by Sir Victor Horsley's evidence, but of "Accidental Death." Sir Victor Horsley went home and wrote to the *Times*, and was replied to by Mr. Troutbeck, other gentlemen taking part in the controversy. Various allegations and counter-allegations were made, and the editor, as the result of the controversy, in a leading article discussed the position taken up by Mr. Troutbeck, finishing with the words of Dr. McManus, who had contributed a letter, "Surely it is high time for the Lord Chancellor to intervene."

Lord Loreburn has proved himself to be a man possessed not only of great ability and a high sense of public duty, but of reforming zeal where abuses which he can control occur in the sphere of his jurisdiction. We appeal to him to consider if it is not urgently necessary to hold an inquiry into Mr. Troutbeck's public acts as coroner. The points to which we submit inquiry should be directed are as follows: (1) Is Mr. Troutbeck by temper and temperament fitted for a judicial position? It is publicly asserted by leading practitioners in South-West London that he is actuated by animus against the medical profession. It is plain he is obstinate, but he is actuated merely by wrong-headedness or by motives improper in a man holding his office? (2) Why did Mr. Troutbeck single out the particular case cited above as one in which to start a new policy, namely, that of holding inquests on all patients who die after operation? Mr. Troutbeck has been a full coroner for five or six years. Many deaths after operation have occurred in his district during that time: he says himself that fourteen have occurred this year at the Bolingbroke Hospital. Why did he select the fifteenth as the one for the first inquiry? We have no special knowledge, but we presume that the case under notice is probably the first and only time that Sir Victor Horsley has had a patient in the Bolingbroke Hospital, or, at any rate, the only time he has had a death after operation there. Sir Victor Horsley was the protagonist in the impeachment of Mr. Troutbeck before the late Lord Chancellor in 1904. Was it merely a coincidence that he should have been the surgeon who first came under the rule, or were there other motives? The latter has been publicly suggested ,and if correct the matter is of the utmost gravity. (3) Why does Mr. Troutbeck always employ Dr. Freyberger, who lives in North-West London, to do post-mortems and give evidence at inquests in the South-West? The seven other London coroners found it necessary to call in special pathologists in forty-six cases in the two years 1903 to 1905. whereas Mr. Troutbeck called Dr. Freyberger in 816 times during the same period? Instances of miscarriage of justice are freely alleged, owing to the system, and Dr. Freyberger's attainments as a pathologist are called freely into question. We say that matters having got to this pass, the restoration of public confidence in the administration of the South-West London Coroner's Court can only be restored by a judicial inquiry by the Lord Chancellor, or some independent tribunal appointed by him, and we appeal to him to take the matter into his serious consideration. No other avenue is open except that of personal appeal to him. His predecessor expressed disapproval of Mr. Troutbeck's methods, and since then they have been developed in new or alarming directions. Indeed, we cannot see how Lord Loreburn, consistent with the respect due to his high office, can any longer refrain, and we believe that he will not allow matters to drift on now that his attention has been specifically directed to them.

CURRENT TOPICS.

The Council Election at the Royal College of Surgeons, England.

The time having expired for the nomination of candidates for election to the vacancies on the Council of the Royal College of Surgeons, we are now enabled to publish the full list of those who will compete for the suffrages of the Fellows. The retiring Councillors are Mr. Pearce Gould and Mr. Harrison Cripps—the former, of the Middlesex Hospital, the latter, of St. Bartholomew's Hospital will seek re-election, while the names of the other candidates, in alphabetical order—seniority is not an element of much concern in these elections—are Mr. George Eastes (date of Fellowship, 1868), Mr. W. F. Haslam (1881), Mr. Arbuthnot Lane (1882), Mr. C. B. Lockwood (1881), Mr. Bilton Pollard (1881), and Mr. Lynn Thomas, C.B., J.P. (1892). Thus it will be seen that for the four vacancies declared there will be eight candidates, all but two of whom, namely, Messrs. Haslam and Lynn Thomas, belonging to the metropolitan district. Particularising the new candidates, Mr. George Eastes is presenting himself in the interests of the Fellows of the College who are in general practice, and we hope he will be warmly supported on that ground. Hitherto the occasion has been a very exceptional one on which a representative of the general body of the profession has been elected to the Council. The last election of the kind was that of the late Mr. Septimus Sibley, who was a member of the Council between the years 1886-1891. Mr. W. F. Haslam is the well-known Birmingham surgeon, who, as a representative of the provincial Fellows, should secure a large measure of support. Mr. Arbuthnot Lane, of Guy's Hospital, will appeal to a large constituency of Guy's Fellows, as a prominent metropolitan surgeon; and the same may be said of Mr. C. B. Lockwood, whose connection with St. Bartholomew's Hospital will doubtless secure him many votes. Mr. Bilton Pollard, of University College Hospital, is another Metropolitan surgeon, who also undoubtedly will command a large following. There is also Mr. Lynn Thomas, C.B., J.P., the well-known surgeon of Cardiff, for whom the profession has recently felt a good deal of sympathy in the result of the unfortunate trial in which he was involved at the High Court. This sympathy and the fact that he is a representative of the Provincial Fellows, should tell greatly in his favour at the coming election. The result of the poll will be looked forward to with some interest, owing to the large number of candidates competing. It will not, however, be attended with any political significance, inasmuch, since the Association of Fellows suspended their work, no questions of policy directly affecting the Fellows has disturbed the even tenor of the Council's deliberations. This being the case, therefore, the suffrages of the Fellows in these elections are now chiefly disposed of in favour of the various candidates upon private grounds and considerations of friendship. The election will take place in the library of the Royal College of Surgeons, Lincoln's Inn Fields, on Thursday, July 2nd, previously to which every fellow of the College, whose address is known, will have received a voting paper for the purpose of recording his vote for transmission by post, instead of requiring him to attend personally at the College.

The Prevention of Puerperal Mortality.

The President of the Irish Medical Association, Sir William Smyly, rendered a valuable service to the country at large when he called attention in his inaugural address to the present condition of midwifery practice. He showed that in spite of the fact "that the old type of medical practitioner and trained midwife, actively hostile, or aggressively scornful, with regard to antiseptic precautions, had passed away, and the modern practitioner and midwife were fully convinced of their value," "the mortality of childbirth was nearly double in private practice what it was in well-managed hospitals." The President further said that he considered the Midwives Act was a good one, and that its extension to Ireland would benefit poor lying-in women. There is no doubt that, in private obstetrical practice there is still not only room, but urgent need, for improvement. Much has been gained by the diffusion of the knowledge of antisepsis and asepsis, but on the other hand, the knowledge that they provide a comparative immunity from septic infection when strictly practised, has led perhaps to an undue freedom in performing obstetrical operations. Prevention is better than cure, and the avoidance of unnecessary vaginal manipulations and operations during labour is a far safer mode of avoiding infection than is the more or less perfunctory carrying out of aseptic precautions. Perhaps the best advice that can be given to the country practitioner or midwife on the conduct of labour cases is not to use the strictest aseptic and antiseptic precautions and to wear rubber gloves, but to manage their cases in such a manner that the patient would be safe even if they neglected both these precautions—that is to say, to avoid all intravaginal manipulations. Such a course is possible in every normal case of labour.

The Irish Universities' Bill.

The Irish Universities' Bill has been in a comparatively dormant condition during the past week owing to the Whitsuntide recess, and any public references to it have been, not in Committee, but at different public meetings which have been held through the country and in the columns of our lay contemporaries. One of the most interesting of the latter references is to be found in a letter from the Roman Catholic Bishop of Limerick, which appears in the *Freeman* of Saturday last. It has been very obvious up to the present that the Catholic Hierarchy have not, as a body, pronounced any opinion on the Bill. This omission is all the more noteworthy inasmuch as in the past they have been most prominent in keeping the condition of University education in Ireland before the public. The Bishop of Limerick's letter is therefore certain to attract attention, and, if it is to be taken as representing the opinions of his episcopal brethren, it may well make the Committee of the House of Commons consider whether all its labours are in vain. Its general gist may be judged from its last sentence:—" . . . It weighs very much on our minds that this University Bill, which, within the limits even of the Nonconformist conditions, might be made a tolerable useful measure, is, whether through the unavowed anti-clericalism of some of our politicians, or more political subserviency, being carried through in a shape which will doom it to failure."

The Dangers of Spiritism.

Father Bernard Vaughan has lately devoted one of his characteristic discourses to the subject of "Spiritism." He describes it as a growing evil, and gives his personal experiences—"convincing and distressing proof"—of the dangers to spiritual, moral and physical health which are incurred by many votaries of the fashionable cults of the day. It is too much to hope that Father Vaughan's warning will have any appreciable effect. It is astonishing that at this period of the twentieth century vast masses of the people of every rank should display a credulity as gross as that existing in the days of witchcraft and mediæval thaumaturgy. We are at the present day witnessing the apotheosis of the quack. No pretentions of the most blatant impostor fail of acceptance if only advertised and be-puffed with sufficient impudence and persistence; and no fanatic protagonist of a new religion remains long without a following if he possesses the strength and the means to proclaim his pretensions with enough noise and excitement. The game of curing disease by miracle-mongering engages the abilities of numbers of impostors, and there can be no doubt their practices in many cases lead to the results that Father Vaughan deplores. The emotional debauches which the cure by miracle provide for the neurotic and hysterical, and for the class who may be said to have made the first step towards the lunatic asylum, often lead those wretched sufferers to the terrible destination from which judicious treatment might have saved them; and with this fact most practitioners, and probably all specialists in mental disease, are nowadays too familiar. Much medical imposture, including that masquerading under the cloak of religion, might be put an end to by legislation. Perhaps this may be done some day when the whole story shall have been unfolded before our responsible statesmen.

Clumsy Milk Adulteration.

Since the introduction of the three per cent. standard for fat in milk, there has been some temptation to a small class of men engaged in the milk trade to add sufficient water to their milk to enable it just to scrape through the test. Should a farmer or milkman be desirous of knowing the amount of fat in his milk, he need not go to any considerable expense over the matter, as certain agricultural colleges will give him this datum for the very professional fee of sixpence. Far be it from us to suggest that such cheap analysis is abused in the manner indicated, we merely suggest that it might be. At all events, however, the amount of the milk fat is obtained, a simple rule of three sum, such as most highly educated people can worry out in time, will give the precise amount of water that can with safety be added. We will not waste time over a lament on the way in which the higher mathematics and analytical chemistry can be used for base purposes, but will pass on to the consoling reflection that the addition of water lowers the percentage of non-fatty solids in milk, and the composition of milk is such that the reduction of the fat to three per cent., has on occasion so reduced the amount of non-fatty solids, that despite the mathematical and analytical aid, the finer susceptibilities of the milkman have been pained to receive an intimation that his milk has been certified as adulterated by the public analyst. According to Mr. C. G. Moor, the Public Analyst for Dorset, a brilliant thought has struck a London milkman. The latter genius added to his milk a mixture of sugar and starch paste which had the effect of keeping up the non-fatty solids figure. Unfortunately for the sophisticator's ingenuity starch paste can readily be detected by the addition of iodine solution, and he must now find some less readily detectable substance for his purpose. In justice to the milk trade generally, we must admit that such clumsy adulterators are comparatively rare, and probably if cases of milk adulteration were traced home it would be found that a very large proportion of them are due to dishonest employees.

The Administration of Anæsthetics.

In our last issue we made reference to the administration of anæsthetics by persons who are not qualified medical men, and we are glad to find that the same subject was matter of discussion at the recent session of the General Medical Council. That body had previously taken the important step of recommending to the licensing bodies the inclusion of the art of administering anæsthetics among the subjects of instruction in the medical curriculum. We have to deplore the tendency to cram any more subjects into an already over-crowded curriculum, and while we regard instruction in anæsthetics as a necessity, we must wish that some of the more useless subjects of the course were dropped. At the recent session, in reply to a communication from the Medico-Legal Society the Council promised its support to any measure which would limit the administration of anæsthetics to qualified and registered practitioners

In the protection of the public some legislation to this effect seems necessary. At present anæsthetics are given with impunity by quack dentists or, what is almost more scandalous, by the mechanical assistants of qualified dentists. When a patient is killed, as not infrequently happens, the perpetrator of the crime is usually acquitted, the judge and jury accepting suborned statements of his experience as proof of his competence.

The British Dental Association.

The meeting of the British Dental Association held last week in Belfast was one of much interest, whether judged from the scientific or the social side. The importance of the care of the teeth to the health of the body is becoming more widely recognised day by day, both by physicians and by dentists. The physician knows that in many diseases he cannot hope to effect a cure until the mouth has been put into a hygienic condition. On the other hand, the dentist is no longer a mere mechanic, but has become a scientific worker, and he regards his art as part of the general art of surgery. Amid the other work of the meeting last week there was found for the public a lecture on "The Teeth of the People: A National Asset," delivered by Mr. Leonard Matheson. It was clearly shown to what a degree the health of the nation depends on the condition of the teeth, and the simpler prophylactic measures to prevent caries were detailed. Other papers of less general, though not smaller, interest were read in the general session, and so active were the discussions that several papers were crowded out through lack of time. On the social side there were many pleasant re-unions, including a party to the Giant's Causeway. Those who were present at the meeting will, we believe, carry away pleasant recollections of Belfast.

The Irish Medical Association.

The annual meeting of the Irish Medical Association, held last week in Dublin, was fairly well attended, and considerable business of importance was transacted. The report, however, showed a deplorable falling off in the membership. There were only eleven new members elected, whereas eighteen old members resigned, and thirteen died, showing a decrease of twenty in the membership. There are something like 2,500 medical men resident in Ireland, and of these only 726, a little more than a fourth, are reckoned as members of the Association. Moreover, of these 54 are two years' subscription and 104 one year's subscription in arrears. The true membership, therefore, can hardly be regarded as more than 650. It is necessary to ask for the reason of this, and for the great falling off during the past few years. Undoubtedly, on the one hand there is considerable apathy on the part of the rank and file of the profession as to any united action. On the other hand, we cannot acquit the present executive of mismanagement and carelessness which has contributed to this apathy. The organisation of the Association is obsolete, the expenditure has been injudicious, and all attempts at reform are blocked. Unless the Association seriously takes the matter in hand, and that speedily, we see nothing before it but gradual extinction.

PERSONAL.

Princess Louise Augusta, of Schleswig-Holstein, presided at the annual meeting of the supporters of Friedenheim Hospital (Home of Peace for the Dying), on Saturday last.

Mr. J. Rymer Young, of Warrington, has been re-elected President of the Pharmaceutical Society of Great Britain.

Princess Christian, attended by Mrs. Dick-Cunyngham, visited Caxton Hall, Westminster, and presided over the annual meeting of the Royal British Nurses' Association

The Executive Committee of the Council of University College. Bristol, have conferred the Associateship of the College on Philip G. Stock, M.R.C.S., L.R.C.P., D.P.H., Assistant Medical Officer of Health and Justice of the Peace, Johannesburg.

Sir William Whitla, M.D., LL.D., has consented to deliver the Cavendish Lecture before the West London Medico-Chirurgical Society on the evening of June 26th, in the Town Hall, Kensington. Subject: "The Ætiology of Phthisis." A *conversazione* and exhibition will follow the lecture.

The Committee of the Liverpool Royal Infirmary announce a gift of £10,000 from the executors of the late Mr. E. R. Bickersteth, their Senior Honorary Consulting surgeon. In accordance with the donor's wishes, the money is to be devoted towards the provision of an improved and extended out-patients' department.

Dr. Theodore Charles Mackenzie, Senior Assistant Physician, Royal Asylum, Aberdeen, has been appointed Medical Superintendent of the Inverness Asylum.

The Right Hon. Sydney Buxton, M.P., Postmaster-General, is to be the guest of the British Postal Medical Officers' Association at their annual banquet at the Hôtel Métropole on July 14th. Dr. George A. Mason, President of the Association, will be in the chair.

Mr. John Hayward will open a discussion on the recent memorandum of the Board of Education on the medical inspection of school children, at the annual general meeting of the Medical Officers of Schools Association in London to-morrow night.

Sir James Sawyer, M.D., F.R.C.P., will preside at the dinner at the Grand Hotel, Birmingham, on the evening of Saturday, June 20th, to celebrate the provincial meeting of the Society for the Study of Disease in Children, to be held in the city that day.

On the recommendation of the Secretary for Scotland, His Majesty has approved the following appointments:—Professor Samson Gemmell, M.D., Professor of Clinical Medicine in the University of Glasgow, to be Professor of Practice of Medicine in that University, in the place of the late Sir T. McCall Anderson; and Mr. Francis Mitchell Caird, Lecturer on Clinical Surgery in the Royal Infirmary, Edinburgh, to be Regius Professor of Clinical Surgery in the University of Edinburgh, in the place of the late Professor Annandale.

A CLINICAL LECTURE

ON

HOW TO DISTINGUISH THE DIFFERENT VARIETIES OF CHRONIC DEAFNESS.

By PROFESSOR ARISTIDE MALHERBE, M.D.,

Surgeon to the National Institute for Deaf Mutes, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

IT is often of great advantage to the practitioner to be able to identify the principal ear diseases instead of contenting himself with a vague or merely symptomatic diagnosis. It is the same in respect of ear diseases as with diseases of other organs. A doctor who, when confronted with a case of tubo-tympanic catarrh, for instance, merely describes it as "deafness," is on a par with one who, in the presence of typhoid, diagnoses "fever." I propose in this lecture to explain how, by simple clinical examination, without the aid of any instruments save those that every practitioner almost of necessity possesses, among which the tuning fork must be included, it is possible to arrive at an exact diagnosis of chronic affections of the ears, the principal symptom whereof is diminution or loss of hearing.

In chronic maladies of the auditory apparatus there are a certain number of symptoms which are common to many of them, viz., deafness, noises in the ears, and vertigo. Deafness, or rather some diminution of the faculty of hearing, is, however, the most common, and is the first to attract attention. What we require to know is how and why the patient is deaf. The future of the patient's hearing depends on this diagnosis, and every practitioner can elucidate this point easily enough without being obliged to have recourse to the technical methods employed by specialists.

When we are consulted by a patient who comes complaining of not being able to hear, how are we going to determine what affection he is suffering from? Before any examination, just as in any other disease, we must question him. And what must we ask? There are two principal questions that must be put forthwith. The replies to these two questions will teach us at once whether or not we are dealing with an inflammatory affection. First of all we must ask him what he has been suffering from either at the time or previously, and under the term of suffering must be included noises in the ears, which may be very troublesome, although not strictly speaking of the nature of "suffering."

Next we must ask whether or not there is, or has been, any running from the ears. If the patient replies in the affirmative we know that we are dealing with an inflammatory affection of the ears. With that I do not propose to deal on this occasion. If, on the contrary, he replies in the negative, his affection is non-inflammatory. The next step is to diagnose the kind of deafness he is suffering from, and with this object in view we ask him whether the deafness is of long standing. If the deafness came on suddenly, more or less suddenly after a bath, after the introduction of a liquid into the ear, or from any other cause, the likelihood of an accumulation of wax will suggest itself, and this point can be cleared up at once by direct examination.

If the patient states that he is deaf, but not always to the same degree, that he sometimes hears better or worse than at others, we must proceed to investigate the state of the Eustachian tubes. We must make a careful examination of the thoat, looking out for evidence of rhino-pharyngeal catarrh, with or without secretion, or adenoid vegetations. We must also examine the nose to ascertain whether he has had repeated attacks of coryza, or hypertrophic or atrophic rhinitis, simple or multiple deviations of the septum, the turbinates, and other causes of permanent obstacle to nasal respiration. In these cases the lesions of the nasal mucosa are propagated to the Eustachian tubes very slowly, by recurrent attacks, but in the long run the result is certain.

Then we examine the tympanum by the aid of a speculum. It may be more or less depressed (concave), with the handle of the malleus raised and a salient external apophysis, all of which admit of recognition with a little attention. Depression of the tympanum is due—the Eustachian tube being obstructed—to the pressure of the column of air and also to adhesions in the tympanic cavity which fix the ossicles. The classic test introduced by Valsalva, blowing air into the ear by means of Politzer's bag, will confirm the diagnosis. (I purposely avoid mentioning catheterism of the tube, in spite of its practical importance, because it can only be employed by persons with considerable experience.) There are cases to which the term tubo-tympanitis my be applied, *i.e.*, affections in which the lesions are mostly located in the Eustachian tube and tympanum, such lesions being characterised by thickening and the formation of adventitious fibrous bands that hinder the free play of the ossicles, and may degenerate into sclerosis. These cases of tubo-tympanitis ultimately merge into secondary tympanic sclerosis, of catarrhal or infective origin, which spreads from the rhino-pharynx to the tympanic cavity *viâ* the Eustachian tubes. In their simplest form they constitute ***tubo-tympanic catarrh,*** while in the old-standing fibro-ankylosing variety we are dealing with ***hyperplastic otitis.***

Let us assume that we are dealing with a patient who presents no obstruction of the external auditory canal or Eustachian tube, who has been deaf for several years—ten years and upwards. He tells us that there are places where he hears better than in others—in the train or omnibus, for instance. This stamps it as a chronic affection of the tympanic cavity.

We must then ask our patient at what age he began to be hard of hearing. If he tells us that it was in early life, say, between 18 and 30 years of age, especially if the patient be a woman, we must question her closely as to her hereditary antecedents, and we shall often find out that her father or mother, brothers or sisters, have suffered from rheumatism or have died of tuberculosis. With respect to the patient himself, we may find that there have been attacks of pain in the fifth nerve, fugitive or persistent headaches, auditory hyperæsthesia, or there may have been pseudo-rheumatic manifestations (intercostal or sciatic pain, lesions of bone, scoliosis, etc.).

On examination, the tympanum, as a rule, presents little alteration, at most a little redness of the inner part of the tympanic cavity. The Eustachian tube is patent. What, then, is our patient suffering from? It is one of the commonest affections, one that was long confused with sclerous otitis, and which is known as early adhesive otitis. Its principal feature is true ankylosis of the stapes, a typical articular synostosis of the same kind as ankylosing tuberculous rheumatism.

Following up our inquiry, we find that the affection began with deafness and noises in the ears or, it may be, quite insidiously without any noises, and without any pain. In some cases these symptoms are accompanied by pseudo-rheumatic manifestations. The disease runs a more or less rapid course, there being periods of arrest, followed by sharp outbreaks associated with headache. The noises in the ears and the deafness then increase in intensity, and these recrudescences are specially apt to supervene at the menstrual periods, or during pregnancy. The process of ankylosis progresses little by little, the diminution of hearing becomes more pronounced, and the deafness affects both ears, though possibly in different degrees. These are the principal signs that enable us to identify this affection, so often overlooked.

Let us now take the case of a patient somewhat advanced in years. He complains of noises in the ears and deafness, or deafness only. In his hereditary antecedents we get a history of neuro-arthritism or arthritism, arterio-sclerosis or gout. On examination we find that the lesions are essentially of vascular origin, involving, so to speak, the whole ear, external, middle and internal. The external ear is often very flat, not much convoluted, parchment-like, angular, and with little in the way of a lobule. The external auditory canal is large and straight, and its walls are persistently dry. The tympanum is sometimes thickened, opaque, sometimes greyish and translucent. It may be infiltrated with calcareous salts and be remarkably rigid, while in other instances it is relaxed and thinned. Inside the cavity there are incrustations or calcareous deposits. The Eustachian tube is abnormally wide, owing to atrophy of the mucous membrane. This affection is almost always bilateral and runs a slow insidious course. In the long run it ends in sclerosis of the labyrinth when the panotitic process is complete and deafness is absolute. This variety, which we may call scleromatous otitis *ab origine,* to distinguish it from the preceding variety, is easy to identify by the signs just described. These two last forms of deafness—adhesive and scleromatous tympanitis—belong to the group of the tympano-labyrinthian affections, which are distinguished from tubo-tympanitis by the fact that the lesions, instead of spreading through the Eustachian tube, start within the ear itself, and involve at or about the same time the tympanic cavity and the labyrinth, whence their special gravity.

There is one other category of deaf people who do not present any of the symptoms previously described. These are cases of labyrinthian deafness. They can be distinguished by means of the tuning fork. If patients hear nothing when we apply the tuning fork to the skull the deafness must be due to some cerebral lesion (meningitis, tumour, etc.). If they still hear, but perception is almost abolished, this is a sign that the mischief is in the labyrinth. This is what used to be called "nervous otitis." An inquiry into the disturbances of which these patients complain will put us on the track. Moreover, in otitis of the labyrinth the noises in the ears are very loud and there is vertigo.

These, then, in synoptic form, are the principal signs that enable every practitioner who will take the trouble to identify the particular form of deafness from which a patient is suffering, and this, too, by means of the simplest possible clinical examination without any unusual skill or special instruments.

The synoptical table hereunder comprises the various forms of deafness just described:—

External Ear	**Auditory Canal**	**Wax**
		Foreign Bodies
Middle Ear	**Tubo-Tympanitis**	**Tubo-Tympanic Catarrh**
		Hyperplastic Otitis
	Tympano-Labyrinthitis	**Early Adhesive Tympanitis**
		Scleromatous Tympanitis *ab origine*
Internal Ear	**Labyrinthitis**	**Tumours**
		Syphilis
		Meningitis, &c.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Robert A. Fleming, M.A., M.D., F.R.C.P.Ed., Physician to the Edinburgh Royal Infirmary, Lecturer on the Principles and Practice of Medicine in the Edinburgh Medical School, Examiner in Medicine, Aberdeen University. Subject: "Sciatica."*

ORIGINAL PAPERS.

ON THE DANGERS AND TREATMENT OF MYOMA OF THE UTERUS.(a)

By CHRISTOPHER MARTIN, M.B.Edin., F.R.C.S.Eng.,
Surgeon to the Birmingham and Midland Hospital for Women.

LECTURE II.

In my first lecture I discussed the various dangers of myoma, and the complications that may arise. I also pointed out the slender hope there was of a natural cure, by extrusion of the growth per vaginam, by absorption after confinement, or by atrophy at the menopause. To-day I propose to direct your attention to the treatment of the disease.

We may divide the various remedial measures into the medical and the surgical. Let us first consider the medical (or non-surgical) methods of treatment.

I.—Non-Surgical Treatment.

If a patient has only a small myoma, which is not growing, not causing pain, severe hæmorrhage, or interference with her health or comfort, we are not justified in advising her to undergo an operation. The case should be watched, and the growth examined, at regular intervals, to see if it be really quiescent. A fibroid which is not actively growing, may yet vary in size from time to time, being larger and more vascular just before the period, and smaller after it. This is most noticeable in those cases where there is much menorrhagia. Hence, to ascertain if the tumour be really growing or not, it should be examined at the same time after each period—say one week after the cessation of menstruation.

Rest.—It is important that a patient, with a troublesome myoma, should rest as much as possible. During the period, she should stay absolutely in bed. If there be a tendency to flooding, the foot of the bed should be raised, from twelve to eighteen inches, on blocks. In the intervals between the periods, she must avoid all strain and fatigue. Any physical exercise, if at all violent, may bring on sudden and alarming bleeding. Hence dancing, horse-riding, and cycling must be forbidden. One of my myoma patients lived in the country and used to cycle a good deal. She found that, whilst walking never brought on hæmorrhage, cycling frequently did so; and, on one or two occasions, caused such a severe flooding that she fainted on the road, and had to be carried home.

(a) **Abstract of the Ingleby Lectures delivered at the University of Birmingham on May 7th and 14th, 1908.**

If the patient be married, she should be warned of the dangers of pregnancy. In these cases, I think it is our duty to tell the woman and her husband to take suitable measures to prevent conception. In all cases of polypus, in most sub-mucous, and in many interstitial fibroids, it will be found that sexual intercourse is apt to start hæmorrhage. In such cases, coitus must be forbidden.

Supporting the Uterus.—The patient should be forbidden to wear corsets, as they tend to press the tumour down into the pelvis. At the same time, by obstructing the abdominal veins, they keep up a condition of chronic venous congestion in the uterus, and so favour hæmorrhage. On the other hand, the wearing of a light abdominal belt is sometimes beneficial, especially where the tumour is subserous, of large size, and is pressing on the bladder, the pelvic veins and nerves. Here, a well-fitting belt may comfort her, by taking some of the weight of the tumour off these structures.

It is sometimes useful to support the uterus from below by means of a pessary—especially in those cases of small myomata which cause retroflexion and retention of urine. In such cases, the urine should be drawn off with a catheter, the patient placed in the genu-pectoral position, the impacted tumour pushed up out of the pelvis, and a large ring pessary adjusted.

Drugs.—The treatment of myoma by drugs is unsatisfactory, and resolves itself into the alleviation of symptoms. By far the most important of these is hæmorrhage.

Ergot is our chief remedy for the control of the bleeding; and, in many cases, is of great value. It excites the contractions of the uterine muscle, and, by pressing together the opposing surfaces of the mucosa, checks excessive bleeding. To some extent, it also acts by causing contractions of the small arterioles. I know of many cases, where patients have taken ergot in drachm doses thrice a day for years; and I have never seen it produce ergotism. Its use, however, is not free from objection. As Dr. Thomas Wilson has pointed out, when the heart muscle is degenerated, ergot is contra-indicated. It contracts the arterioles all over the body, and so increases the resistance to the left ventricle. The liquid preparations of ergot sometimes upset the digestion. In such cases, it will be found that ergotine, given in pill or tablet form, agrees better with the stomach. It may be given hypodermically; but there are many objections to this as a regular mode of administration. It is painful, and, if not given with aseptic precautions, may give rise to small abscesses at the seat of puncture. In emergencies, however, as when a patient is flooding severely and prompt action is necessary, a sterile preparation of ergot, given hypodermically, is of great value. But, beyond controlling the hæmorrhage, I doubt if ergot has any good effect on a myoma. The uterine contractions, which it excites, tend to convert an interstitial fibroid into either a subserous or submucous one. If the latter, whilst it is true that the growth becomes more accessible from the vagina, the tendency to flooding is increased. In any case, I think the prolonged use of ergot predisposes to degeneration and necrosis of the fibroid, by interfering with its blood supply.

Hydrastis is often prescribed with ergot in the form of tablets. It is an astringent to the uterine mucosa, and so helps to check the menorrhagia and leucorrhœa due to the endometritis so often present. As far as I know, it has no direct effect on a fibroid.

Cotarnine is a derivative of morphia, and, in the form of styptol, has been recommended in cases of myoma. I have tried it in several cases; but I cannot say I have seen much benefit result.

Calcium chloride has the property of increasing the coagulability of the blood, and in this way favours the natural arrest of hæmorrhage. It is thus undoubtedly of service in bleeding fibroids.

Bromide of potash, iodide of potash, and chlorate of potash have all been advised in myomata, but I doubt if any of them do real good. Lawson Tait, following Sir James Simpson's teaching, was in the habit of treating most cases of metritis, subinvolution, and small myomata with chlorate of potash combined with ergot. He claimed that it was a sedative to the uterus, and caused absorption of chronic inflammatory deposits. All the potassium salts are muscle-poisons, and tend to weaken the uterine contractions. But, for the same reason, they are also heart depressants; and, where the heart is failing, may do positive harm. Bromide of potash may be of service in allaying nervous irritability, and in promoting sleep. I have never seen any benefit result from the administration of iodide of potash, or indeed any of the preparations of iodine. I am sceptical, therefore, as to the virtues of the iodine and bromine waters of certain spas, such as Woodhall, Kreuznach, etc. Undoubtedly, many patients return benefited from a visit to such health resorts—especially if there was not much the matter when they went. The change of air and scene, the freedom from home worries, the mental and physical rest enjoyed, and the regulation of the patient's diet, bowels, and habits of life—to these factors we must give the credit of whatever improvement takes place.

Tonics.—When a patient is anæmic, weak and exhausted, it is customary to give her tonics, especially iron. Whilst iron picks the patient up, and stimulates the blood-forming organs, it may prove a dangerous remedy by exciting alarming hæmorrhage from the uterus. It often does far more harm than good. The organic preparations of iron—such as the peptonate—seem to be less hurtful than the inorganic metallic salts. In cases of profound exhaustion, it is safer to give strychnine, strophanthus, easily assimilated preparations of phosphorus, and, above all, the various preparations of hæmoglobin.

Laxatives.—A myomatous woman should keep her bowels well open, as constipation tends to increase congestion of the uterus, through scybala pressing on the ovarian veins. Straining at stool may bring on hæmorrhage from the uterus. Further, fibroids frequently cause piles from pressure on the rectum; and these, as a rule, are aggravated by constipation. Some mild laxative, such as cascara, sulphur, compound liquorice powder, or a saline aperient water, should be ordered.

Vaginal Plugging.—Plugging the uterus and vagina is of great help in controlling dangerous bleeding. It may tide a patient over a bad flooding, and allow her to gain some strength before undergoing an operation. When called to a patient collapsed, blanched, and nearly pulseless from uterine hæmorrhage, it is madness to attempt a big surgical operation such as hysterectomy. The best treatment is to put her on her side, pass a Sims speculum, and draw down the cervix with vulsella. If the cervix be found dilated, the uterine cavity should be firmly plugged with a long strip of iodoform gauze. The first few inches of gauze may be soaked, with advantage, in a solution of adrenaline. The rest of the vagina should then be firmly plugged with some antiseptic material, such as iodoform gauze, or dry boracic lint. A firm abdominal binder should be applied to exert counterpressure on the uterus. The plugging should be removed from the uterus and vagina every 48 hours, and fresh material re-applied. In this way the bleeding is controlled, and the patient given time to rally. Should the myoma be submucous (and these are the cases in which there is most bleeding), the gauze packing slowly dilates the cervix, and renders easy the subsequent removal of the growth.

It is most unwise to apply styptics, such as alum or perchloride of iron, to the interior of the uterus to check bleeding. They lead to the formation of hard clots, which, decomposing, cause sepsis, and precipitate the onset of necrosis.

Electrolysis.—There is a mystery—a glamour—about electrolysis, which allures patients who have a horror of the knife, and who grasp at any alternative which promises relief. As a means of treatment, it has been given a careful trial by scores of gynæcologists, and has now been abandoned as futile and dangerous. Vineberg analysed Keith's and Engelmann's statistics, and found that, out of 372 cases, there were 5 deaths and only 9 cures. Martin and Mackenrodt report 36 cases, of which 16 were distinctly made worse, and 3 died—one from pulmonary embolism, one from necrosis, and one from suppurative peritonitis. In some cases temporary benefit was obtained in the arrest of hæmorrhage from the congested endometrium. But when the treatment was stopped the symptoms returned. In other instances, especially where the electrode was thrust into the growth, acute necrosis of the tumour occurred, and endangered the patient's life. It seems to me just as rational to thrust a red-hot poker into the heart of a myoma and expect a cure to result.

II.—SURGICAL TREATMENT.

Bearing in mind the manifold dangers and complications that threaten the myomatous woman, the slender hope there is of a natural cure, and the inadequacy of non-surgical remedies, we are driven to look for help from surgery. I admit it is a choice of evils—no woman wishes to undergo an operation if she can be cured by milder measures. In the early days of abdominal surgery, the major operations for the removal of a fibroid resulted in such a frightful mortality that they were only undertaken as a *dernier ressort*. But now, thanks to a more perfect asepsis and an improved *technique*, modern surgeons can show such a low death-rate that, in the great majority of cases, a radical operation can be conscientiously advised.

Before discussing the merits and de-merits of the various operations for myoma, let me briefly state the indications for and against surgical interference.

Contra-Indications to Operation.—I would not advise an operation:—

(1) Where the tumour is smaller than an orange, is causing no symptoms, and is not growing.

(2) Where the patient is past the change of life, and the myoma is quiescent and causing no trouble.

(3) Where the patient is gravely ill from some other condition—such as phthisis, heart disease, or kidney disease—which will of itself prove fatal before long.

Indications for Operation.—On the other hand, an operation is called for:—

(1) Where there is severe bleeding, uncontrolled by rest and ergot.

(2) Where there is rapid or persistent growth of the tumour.

(3) Where there are signs of degeneration, necrosis, or malignant disease.

(4) In many cases complicated with pregnancy.

(5) In cases complicated with gross lesions of the ovaries and tubes.

(6) Where there are marked symptoms of pressure on the urinary organs.

(7) Where the tumour is very large, and from its great bulk and weight becomes a burden.

(8) In some single women where the tumour, from its size, leads to unfounded suspicions of pregnancy, and causes the patient much unhappiness.

(9) In cases of sterility due to the presence of a myoma, which can be removed without sacrificing the uterus.

No hard and fast rule can be laid down. Each case must be considered on its merits, and the question of operation decided only after due consideration of the condition of the tumour, its rate of growth, the gravity of the symptoms caused by it, and the state of the patient's general health.

The operations for myoma may be divided into: (1) those performed per vaginam; and (2) those that involve abdominal section. Let us first consider the vaginal operations.

Curetting.—Curetting should be performed, after the removal of a fibroid polypus or a submucous myoma, in order to cure the endometritis which generally accompanies these conditions. In some interstitial tumours, if done cautiously and aseptically, it may also do good by checking the leucorrhœa and menorrhagia, and so giving a feeble patient time to regain her strength. It is seldom, however, of more than temporary benefit, and is not without risk. If the tumour be submucous, it may cause necrosis by opening the capsule of the growth, and allowing germs to get access to its structure. Further, in cases complicated with pyosalpinx or ovarian abscess, curetting may be positively dangerous, by the manipulations causing the pus sac to burst into the peritoneum.

Removal of Polypi.—A fibroid polypus should be removed as soon as discovered. It is an easy and safe operation. In most cases, it is enough to seize it with vulsella and twist it off. If the growth be large and the pedicle broad and vascular, it is safer to control the bleeding with a ligature. I usually crush the pedicle with strong Spencer-Wells' forceps, and then tie a fine silk ligature in the groove left by the forceps. Occasionally a fibroid polypus is met with of colossal size, filling the pelvis, and lifting the uterus up into the abdomen. In such cases the growth must be cut away piecemeal, before the pedicle can be reached. Patients with fibroid polypi are often quite blanched from long continued hæmorrhage; but if there be no other complication, they make a rapid recovery.

Vaginal Myomectomy.—Vaginal myomectomy was first performed by Amussat in 1840. The *technique* was developed by Atlee, Emmet, and Thomas, and perfected in recent years by Pean and Doyen. It is the operation, par excellence, for the removal of submucous growth. These are usually, but not invariably, single. They cause very severe bleeding; and, if of large size, block the pelvis, and cause retention of urine. The uterine contractions tend to force the growth downwards, to dilate the cervix, and to convert the tumour into a fibroid polypus. During this process, there is a great risk of necrosis occurring. Hence every submucous tumour should be moved without delay. Where the cervix is dilated, it is usually easy to enucleate these growths, after the mucous membrane and thin remains of the capsule have been divided. If the cervix be insufficiently dilated, it may be split with scissors vertically in the middle line. The growth then becomes accessible, and may be removed either whole or piecemeal (morcellement). The cervical wound may then be closed with catgut, and the uterus preserved entire. It is an ideal method in sterile women anxious to have children; and it is the one always indicated in cases of necrosing submucous fibroids. It is, however, sometimes a long and difficult operation; and the patient may lose much blood before it is finished. It is usually unwise to attempt it, if the tumour be larger than the fœtal head at term. During the years 1892 to 1908, I find that, at the Birmingham Hospital for Women, the operation of vaginal myomectomy was performed in 34 cases, with 2 deaths—a mortality of 6 per cent.

Ligature of the Uterine Arteries.—This operation was introduced by Dr. Franklin Martin, of Chicago; but it has not found much favour in this country. The object is to cut off most of the blood supply of the uterus, to check the menorrhagia, and cause the tumour to atrophy. But there is such a free anastomosis between the uterine and ovarian arteries, that the latter rapidly enlarge; and soon the womb is as well supplied with blood as before. Moreover, a sudden and very marked decrease of the blood supply may cause necrosis of the growth. It is quite an easy operation. An incision is made in each lateral fornix, the enlarged uterine arteries are felt for, exposed, and tied with stout silk—taking care, of course, to avoid including the ureter. I have performed it in two cases, but without any benefit to the patients.

Vaginal Hysterectomy.—It is the best operation to perform in cases of small myomata—other than those which can be enucleated without sacrificing the uterus. It removes the whole of the disease; it does not involve an abdominal scar, and it is attended with but moderate risk to life. In my own practice, hospital and private, I have, up to date, performed the operation for myoma 73 times, with 3 deaths, a mortality of 4 per cent. It may be a dangerous operation when the uterus, with its myoma, is larger than a three months' pregnancy, if it be fixed by adhesions, if the case be complicated by pyosalpinx or ovarian abscess, or if the vagina be very narrow and rigid. In such cases, it is safer to open the abdomen, and remove the uterus from above.

Some years ago, I lost a case by not following these rules. The woman was exhausted by long continued hæmorrhages from a big submucous myoma. I split open the uterus, enucleated the growth piecemeal, and then removed the rest of the uterus by vaginal hysterectomy. The operation, which took about two hours, was a long, difficult and bloody one; and the patient never rallied from the shock. Had I opened her from above, and performed abdominal hysterectomy,, I feel sure I should have saved her.

Abdominal Operations for Myoma.—We now pass to the considerations of the more important abdominal operations for myoma. These fall under three headings:—

(1) Removal of the uterine appendages (where the ovaries and tubes are removed, but the uterus with the tumour is left behind).

(2) Hysterectomy (where the tumour, together with most or all of the uterus, is removed).

(3) Myomectomy (where the tumour is removed, but the entire uterus is saved).

Removal of the Uterine Appendages.—This operation was first performed by Lawson Tait in this city in 1872, and to the day of his death he was its leading exponent. It was, par excellence, "Tait's operation"; and, for nearly a quarter of a century, it held the field against all rivals. It was a fairly safe operation when the tumour was a small one; but a risky and unsatisfactory one when it was large. I find that, during the years 1882 to 1908, it was performed, at the Birmingham Hospital for Women, 300 times with 15 deaths—a mortality of 5 per cent. In my own practice, I have removed the appendages for small myomata 20 times with 1 death (a mortality of 5 per cent.), and for large myomata 8 times with 2 deaths (a mortality of 25 per cent.). I have not performed the operation myself since 1896. In about 90 per cent. of the cases that recovered, menstruation ceased, and the tumour shrank—though I doubt if it ever completely disappeared. But in the remaining 10 per cent. the patient was not cured, the floodings continued, the tumour grew, pressed on the bladder, rectum, and pelvic nerves, and rendered the patient's life a burden to her. Moreover, it was found that, even when the operation removed the symptoms due to the myoma, it often led to others, of a nervous character, equally distressing. Such were intense heats and flushes, palpitation, headaches, nervous depression, and pelvic neuralgia. Some of these patients became neurasthenic wrecks. These sequelæ were no doubt due to the sudden cessation of the internal secretion of the ovaries—something which they manufacture, and add to the blood circulating through them, and which is essential to the well-being of the nervous system.

It was these failures, and bad after-effects, that shook the faith of surgeons in the operation, and led them to search for some more excellent way. When it was found that, by improved methods, we could reduce the mortality of hysterectomy and myomectomy to under 5 per cent., the operation of removal of the appendages was abandoned. None the less should we honour Lawson Tait for his genius in devising this operation, and his courage in advocating it. It was, at the time, a great advance in gynæcology, and it saved thousands of lives that would otherwise have been sacrificed.

Extra-Peritoneal Hysterectomy.—The extra-peritoneal operation was that always performed by Lawson Tait in those cases in which it was impracticable to remove the uterine appendages. The uterus, with the tumour, was delivered through the abdominal wound, transfixed with steel pins as low down as possible, and strangulated, below the pins, with an iron wire drawn tight by means of the serrenœud or "clamp." In some cases, a rubber tourniquet replaced the wire. The tumour beyond the pins was then cut away, and the wound above it closed. The stump underwent acute necrosis, and in about a week became a black, gangrenous, horribly offensive mass. This sloughed off in from ten to twenty days, leaving a huge gaping septic chasm, which took many weeks to close. It was a murderous operation, and those who recovered did so only by the skin of their teeth. They had to run the gauntlet of secondary hæmorrhage, septicæmia, peritonitis, and rupture of the septic wound with extrusion of the bowels. The death-rate was terrible—so great indeed that, in the annual report of the Birmingham Hospital for Women for 1891, the medical staff announced that they had practically abandoned the operation.

On looking over the statistics of the hospital I find that, from 1879 to 1900, extra-peritoneal hysterectomy for myoma was performed 58 times with 20 deaths—a mortality of 34 per cent. In my own practice I have done the operation only 8 times with 2 deaths—a mortality of 25 per cent. My last case was in 1895, after which I adopted the intra-peritoneal method.

Intra-Peritoneal Hysterectomy.—Under this heading we include: (1) pan-hysterectomy, where the whole of the uterus, including the cervix, is removed; and (2) supra-vaginal hysterectomy, where the cervix is left behind. Both methods have their advocates. For some years I clung to pan-hysterectomy as the better operation. Increased experience, however, has convinced me that in most cases supra-vaginal hysterectomy is preferable. It is safer for the patient, and less difficult for the surgeon. The ureters and bladder are less in danger, the germ-laden vagina is not laid open to the peritoneum, and there is less interference with the integrity of the pelvic floor. The chief argument urged against supra-vaginal hysterectomy is that the cervix, which is left behind, may become the seat of cancer. But I do not think statistics support this objection. Therefore, contrary to what I taught in 1896, I now hold that, whenever possible, supra-vaginal hysterectomy should be performed in preference to pan-hysterectomy. The latter should be reserved for cases where the cervix is involved in the myoma, or otherwise diseased.

It is an easy operation, if the patient be thin, and the tumour be confined to the body of the uterus. It may be a very difficult one in a fat woman, or where the myoma has invaded the broad ligament, or developed in the cervix.

Whenever possible, one or both ovaries should be left behind, so as to preserve for the patient their "internal secretion." If one or both can be saved, removal of the uterus causes practically no climacteric disturbances, whilst if both be removed the patient suffers severely. Of course, if both ovaries be diseased, they must be taken away.

The after results of intra-peritoneal hysterectomy are excellent. The patient usually makes an uninterrupted recovery, and gets up, with a soundly healed wound, at the end of a fortnight.

The mortality of the operation is small. In my own practice, private as well as hospital, I have done 51 pan-hysterectomies for myoma, with 2 deaths—a mortality of 4 per cent. I have performed 142 supra-vaginal hysterectomies, with 3 deaths—a mortality of 2 per cent.

Abdominal Myomectomy.—By this we mean the removal of one or more myomata from the uterus by abdominal section, without removal of any part of the uterus. It was first performed by Atlee as long ago as 1844, but I believe this was only the removal of a pedunculated subserous fibroid. The modern operation (in which the tumours are enucleated from the substance of the womb, followed by suture of the uterine incisions and conservation of the whole organ), we owe chiefly to Martin of Berlin, Olshausen, and Kelly. It is the ideal operation for myoma, and will, I believe, ultimately supersede hysterectomy for all but a small minority of cases. It removes the tumour, and leaves the uterus intact. It causes no climacteric symptoms, and, most important of all, it does not sterilise the patient. It may, indeed, cure sterility by removing a tumour, which was preventing conception or interfering with pregnancy. It may be performed during pregnancy without necessarily interrupting the gestation, or adding to the risks of the subsequent labour. In 1891 I was called in to see a case by Dr. Langsford Clay. The patient was æt. 37, and three months pregnant. She had also two large fibroids which were causing great suffering. She had been married for many years without having been pregnant before, and she was very anxious to have a child. I opened her abdomen, made incisions over the tumours, shelled them out of the uterine wall, sewed up the incisions, and closed the wound. The patient made a good recovery. She did not abort, but went to term, and was safely delivered of a living boy.

Here I must draw to a close. Much has been accomplished, but more remains to be done. The end of the nineteenth century witnessed a great advance in gynæcology, notably in the treatment of myoma. In the coming years I look forward to still more glorious achievements by our brethren—those workers for humanity seen in the poet's vision—

> "Ever reaping something new:
> That which they have done but earnest of the things
> that they shall do."

ALCOHOLISM AND CRUELTY TO CHILDREN. (a)

By ROBERT J. PARR,

Director of the National Society for the Prevention of Cruelty to Children.

Amongst the many evils to be attributed to an excessive indulgence in intoxicating liquor, neglect of and cruelty to children is one of the most terrible in its effects. First in sapping the character of parents, whilst killing by slow and insiduous processes the protective instinct of parenthood; then in endangering the life and happiness of a host of children who are being surrounded with an environment corruptive and unhealthy in respect to their physical and moral upbringing; and equally serious as affecting the desires and habits of future generations, as shown by the recurring and increasing deterioration in families of children born to drink-sodden and partially demented parents.

These results are sufficiently grave to excite the careful attention of all intelligent and patriotic people. The man of business, the scientist, the true temperance reformer—all these are concerned, for the evil touches our public and natural life at every point. I have purposely excluded the politician, for he has his own ideas both as to the evil and to the remedy.

The National Society for the Prevention of Cruelty to Children has long since given over trying haphazard methods of reform, and has settled down to what may be described as the application of a scientific system of remedies that are fortunately proving effectual. During the year ended March 31st, 1908, the Society dealt with 46,212 cases reported to it, affecting 134,252 children. Of these cases, 39,867 were due to neglect, and the children neglected numbered 125,674.

There is no exaggeration in the estimate that 90 per cent. of those cases are due to the drinking habits of one or both parents. To all concerned in the treatment of inebriety, it will be encouraging to learn that reform is not only possible, but that it is frequently secured. The Society's records teem with illustrations where under the direct influence of good advice and some watching, parents have given up their habits of drinking, and have resumed normal conditions of life.

The chronic inebriate has also proved to be subject to reform. In England, Ireland and Wales, owing to the action of the Society, 358 inebriate mothers have been committed to detention in Inebriate Reformatories from January, 1901, to March, 1908. Rather more than half of these cases have been reformed. The proportion would have been larger but for the fact that many women were sent away for short periods. Nearly all the women detained were wives whose husbands were earning regular wages, the average ranging from 23s. to 35s. per week.

As in the other class of cases, much depends on the spirit in which the work of reform is undertaken. The personal element is all important as contrasted with the official. Speaking from an experience that justifies testimony, it may be said that though the evil is great, and the difficulties of dealing with it are many, there is boundless hope for ultimate success if only a sufficiently large number of people could be persuaded to give up the pleasure of theorising for the practice of personal help.

(a) Abstract of a Paper introductory to a Discussion before the Society for the Study of Inebriety, held in the Rooms of the Medical Society of London, Tuesday, June 16th, 1908.

CLINICAL RECORDS.

CASHEL UNION HOSPITAL.

SOME SURGICAL CASES UNDER THE CARE OF

THOMAS LAFFAN, M.R.C.P.I., M.R.C.S.Eng.,

Physician to the Hospital.

Case of Fracture of the Right Humerus.

This occurred in P. C., a boy, æt. 9, who was admitted to hospital in February. The fracture was simple, and was through the surgical neck. The point I wish to emphasise is that the splints, which were ordinary ones, were taken off on the tenth day, and passive motion employed. The splints were taken down and re-applied on each tenth day, and light passive motion used. The little patient was discharged on April 2nd with united bone and entire mobility of proximal joints.

Case of Intractable Neuralgia.

C. M., æt. 29, was admitted on January 15th. She had suffered for months from intolerable neuralgia near the outer half of the lower lid. Every possible medicine, both local and constitutional, was tried in vain. At last I resolved on cutting down on the nerves, and commenced with the temporo-facial, where it crosses the lower maxillary condyle, and excised a portion of the nerve. The result was most gratifying. The pain in great part disappeared, and though some remnant remained for a time, the patient was rendered comfortable, while after a little time it disappeared altogether.

Case of Impermeable Stricture.

The patient was æt. 50. It followed an attack of gonorrhœa which he had had many years before. The retention for which I was summoned to him in 1901 was the second of its kind. The other had occurred a few years before. No instrument could be passed, no matter how small. I then used the aspirateur, and emptied the bladder above the pubis. This was repeated at daily intervals for an entire week. At the end of this a delicate whalebone bougie was got into the bladder. Then a minute catheter was slipped in, and the patient in a short time had the stricture fully dilated by the gradual process, and was relieved of all further trouble. He remained well from this affection till his death, which occurred some three years afterwards from Bright's disease.

Excision of Enlarged Glands.

M. S., æt. 25, gardener, was admitted in March, 1904. A number of glands were enlarged on the right half of the neck in the parotid and adjacent portions of the sub-maxillary spaces, posterior superior and posterior inferior triangles, and that portion of the neck covered by the sterno-mastoid. A couple were as large as a hen's egg, and there were all manner of sizes from that downwards. The disease had existed for many months, and a variety of treatment had been tried prior to his coming under my care. On admission his condition was very feverish. On March 20th he was operated upon, and about half of the glands were removed. No untoward symptoms followed. The remainder were removed on May 4th, and the patient was discharged cured in June. I last saw him some twelve months after. In the interval he had been actively engaged in farm work, and he had enjoyed perfect health. On his visit to me his pulse and temperature were normal, and his health excellent. Three glands had enlarged to the size of peas, and, of course, these offered no guarantee against further enlargement. This is the chief drawback of these operations, but, on the other hand, the patients are saved from the exhaustive drain of prolonged suppuration. Even if other glands do enlarge, it seems to me that further operations can be employed without either risk or much ground for grumbling.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Impacted Stone in the Ureter.—Mr. **Arthur Edmunds** operated on a woman, æt. 35, who had been suffering for about 14 days from a swelling in her left loin. This swelling had been increasing steadily in size and had become tender on deep pressure. The accompanying symptoms were largely negative and yielded but little information as to the nature of the swelling. Thus there had been no definite frequency of micturition, no urgency, only once a little scalding, no hæmaturia. There had been, however, signs of severe septic intoxication with rigors, the temperature rising as high as 103° on several occasions. On examining the abdomen a movable swelling could be felt in the left lumbar region, extending upwards under the ribs and backwards towards the spine. The colon could be demonstrated in front of it. There was no rigidity of the abdominal muscles, and the tumour could be moved quite easily for a short distance in all directions. The right kidney was definitely palpable, but not tender, and only slightly more mobile than normal. Per vaginam the pelvic viscera were normal. The diagnosis, therefore, narrowed itself down to some enlargement of the left kidney, complicated by septic infection. The absence of any appreciable quantity of pus in the urine suggested the presence of an obstruction in the pelvis of the kidney, or in the ureter. Accordingly, the kidney was exposed through the ordinary lumbar incision, which was extended downwards into the iliac region; the kidney was brought up into the wound and examined. It was found to be about twice the normal size and extremely congested. On exposing the ureter the fat and connective tissue were found definitely infiltrated about an inch below the junction of the pelvis of the kidney and ureter, and here a definite hard nodule could be felt through the thickened peri-ureteral tissues. Gauze was next packed into the lower portion of the wound to prevent any displacement of this nodule, which was believed to be a stone, and to absorb any pus which might be discovered. The pelvis of the kidney was now opened through an incision about an inch and a half long just behind the convex border of the organ, and about a couple of ounces of purulent urine were let out. The pelvis of the kidney was then thoroughly explored to ascertain if there was any calculus, and an attempt was made to remove the ureteral stone *viâ* the pelvis of the kidney. This was found to be impossible, and accordingly the wound in the kidney was temporarily sutured to arrest hæmorrhage. The ureter was now exposed more fully, and the stone fixed by the finger and thumb of the left hand; a longitudinal incision was then made over the calculus, which was removed, and after the passage of a probe upwards and downwards along the course of the ureter demonstrating that there was no other obstruction the ureteric wound was sutured. The wound in the substance of the kidney was now re-opened to allow a drainage tube to be passed into its pelvis so as to carry off the urine for the first few days, and allow the incision in the ureter to heal. The kidney substance was then sutured firmly around the tube by mattrass sutures of catgut. A convenient instrument for passing such sutures, Mr. Edmunds said, in the neighbourhood of veins is the ordinary fully curved needle passed eye first, thus avoiding much of the hæmorrhage which is caused if the needle be employed in the usual way, the blind end displacing vessels which would otherwise be divided. Drainage tubes were then inserted into the cellular tissue around the kidney, and the incision in the abdominal parietes closed. Mr. Edmunds said that the diagnosis of a kidney tumour was fairly apparent, but it was not clear at first whether there was any perinephric suppuration or not. The absence, however, of any abdominal rigidity and the comparative mobility of the tumour negatived the idea of any such inflammatory mischief, and suggested that the whole of the trouble would be found within the kidney. It was generally worth while, he pointed out, to endeavour to close an incision in the ureter, for although leakage is common, final union is undoubtedly hastened, especially when the urine can be deviated from its normal track for a few days.

The patient bore the operation well, and for the first three days the urine which escaped from the kidney was caught in a vessel by the bedside. When this ceased the amount of urine passed by the urethra suddenly increased from 32 to 50 ounces, proving that the affected kidney was working well, and that there was no obstruction to the passage of the urine. Urotropine was given so as to render the urine as sterile as possible. The septic complications were trivial. The wound healed normally, and a fortnight after the operation the urinary fistula had completely closed, and there was only a slight discharge from the openings of the drainage tubes.

TRANSACTIONS OF SOCIETIES.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Meeting held Thursday, June 11th, 1908.

Mr. R. Marcus Gunn, F.R.C.S., President, in the Chair.

Mr. Priestley Smith showed a small instrument, consisting of a series of lenses arranged in a frame, for use with the shadow test. The feature of the apparatus was the close packing of the lenses, about 16 of them being contained in a linear foot, and it enabled very rapid examinations to be made.

Mr. Leslie Paton showed a case with connective tissue in front of the optic disc.

Mr. Edridge Green exhibited an improved lantern for testing colour-perception. There was an arrangement consisting of three slides in a vertical column, each slide being fitted with variously coloured glasses, which could be brought opposite an aperture with an iris diaphragm.

Mr. J. H. Tomlinson showed a Nernst lamp projecting lantern.

Mr. Sydney Stephenson showed a patient with a curious congenital anomaly of the iris.

Mr. G. W. Roll showed a patient with sky-blue sclerotics, and one with double papillitis.

Mr. Hudson showed a case of Thiersch grafting.

Mr. G. Coats showed a case of exudation in the retina.

Mr. P. E. H. **Adams** read a paper on

AN EPIDEMIC OF CONTAGIOUS CONJUNCTIVITIS DUE TO THE PNEUMOCOCCUS.

He said the epidemic occurred in the spring, in a small school of 37 boys, 21 of whom were attacked. The eldest boy affected was 14, the youngest nearly 10. All the smears taken, except one, showed numerous Gram-positive diplococci. Most of them were typically flame-shaped pneumococci with capsules, though a few of them were rounder in shape, and in some the capsules were not evident. This agreed with the description given by Schmidt ("Archiv. of Ophth.," XXXVII., No. 2) of smears taken from cases of pneumococcal conjunctivitis. On blood agar the colonies were typical slow-growing pneumococci, and there was no growth on agar. Only three of the cases were at all acute, most of them being subacute or quite mild. Four cases of relapse were reported. The condition found on examination was fairly constant: general congestion of the lower palpebral conjunctiva, with slight injection of the ocular conjunctiva, and in the acute cases a thin line of muco-pus in the folds of the conjunctiva of the lower lid. The upper lid showed slight enlargement of follicles at the angles, and a row of minute follicles along the everted edge. The whole epidemic lasted about five weeks, and spread in spite of isolation. It agreed in almost every respect with previously reported outbreaks, the chief difference being the generally mild nature of the cases.

Mr. **Nettleship** read notes of three cases of

HEREDITARY EYE DISEASES.

Case 1 was that of a husband and wife who had senile cataract at an advanced age, and both were operated on with success. They had ten children, and 7 had cataract in various degrees, 2 of these having had them "matured" and operated upon at a much earlier age than in their parents. There were also slight lenticular changes in the grandchildren of the original couple. The second family showed the occurrence of "Coppock," or discoid cataract, and lamellar cataracts of various sizes, and likewise of retinitis pigmentosa. Among about 250 persons the author had been able to trace, belonging to the family, 32 with family cataract, and 15 with retinitis pigmentosa. The sex incidence and mode of descent was shown to be different, for the cataract and retinal disease respectively. The third case was that of a family containing colour-blind individuals. Mr. Nettleship had examined all the available members; and of 33 males 14 were found to be colour-blind: and of 36 females only one was affected, and she slightly. There were 40 others in the pedigree who were either dead or inaccessible.

Lieut.-Col. H. **Herbert** read a note on

SECONDARY (PARENCHYMATOUS) XEROSIS.

He drew attention to the part played by pannus in the development of xerosis after trachoma, and pointed out that old pannus rendered the corneal surface insensitive. Hence, with both corneas covered with pannus, the blinking movements of the lids tended to be imperfect, and thus lead to exposure of the globe. This appeared to be an important factor in the dryness which followed: for in such cases xerosis of the cornea and conjunctiva was often very marked when the cicatricial degeneration of the conjunctiva was much less advanced than in other old trachomatous cases in which the eyes remained moist and the corneas clear. The exposure of the cornea rendered it more opaque and insensitive, so that the blinking movements might amount to only very infrequent and slight twitches of the lids. Similarly inactive lids were seen in India in a few cases of severe primary (epithelial) xerosis. In these cases the exposed cornea became not only opaque, but pigmented, like the degenerate conjunctiva. Here the primarily defective reflex action of the lids seemed to be attributable to malnutrition only. Another factor in the production of cicatricial xerosis was the reduced transudation of fluid from the palpebral conjunctiva. If the upper lid were everted in any case of ordinary acute conjunctivitis, a free flow of watery fluid was readily demonstrable from the exposed conjunctiva. But a similar flow was not obtainable from a cirrhosed or cicatricial conjunctiva, however much inflammation might be present.

Lieut.-Col. **Herbert** also read a paper on

LOWER CORNEAL PLAQUES.

These, he said, were slightly raised, feebly vascular, grey patches with rough surfaces, close to the lower margin of the cornea. Their opacity varied with their thickness. They were often of curious shapes, and were mostly multiple and binocular. They were not very uncommon in India, and appeared to be due to slightly defective closure of the lids, together with more or less chronic conjunctivitis, trachomatous or otherwise.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, JUNE 3RD, 1908.

The President, Dr. **James Ritchie**, in the Chair.

Mr. F. M. Caird showed:—(1) A boy, æt. 14, who had received a crush in the lumbar region causing hæmorrhage into the mesenteric sub-peritoneal tissue and kidney. Paresis of the bowel supervened, necessitating laparotomy and appendicostomy. (2) A patient, æt. 25, who was sent into hospital about 12 hours after rupture of a gastric ulcer. The ulcer was large, situated near the pylorus, and because it was found impossible to secure it very thoroughly, as well as because the operation involved some narrowing of the pylorus, it was deemed advisable to perform a gastrojejunostomy in addition. Until the third day all went well. Then the patient wakened up suddenly from his sleep with severe abdominal pain, and very rapidly passed into a condition of extreme collapse, with cold extremities and an enormously swollen abdomen. Laparotomy was at once performed, and a large volvulus of the ileum, with blackened bowel, was found. Over 10 ft. of intestine were resected, and the patient made a good recovery.

Mr. **Cathcart** showed a woman who was admitted to his ward on account of inability to open the jaws. There was a history that on two previous occasions—1901 and 1904—an operation had been performed to relieve the condition. The case was thought to be one of ankylosis, and injections of fibrolysin having proved ineffectual, operation was determined on. He proposed to remove a wedge from the right side, and possibly from the left. Under chloroform, however, he found that the jaw could easily be opened. A gag was therefore inserted, and the operation was not proceeded with. The patient could now open the jaws perfectly well. The case was looked upon as hysterical.

Dr. W. M. **Russell** read a paper on

CONGENITAL STENOSIS OF THE PYLORUS IN THE ADULT.

Reviewing the history of the subject, he enumerated the various causes of pyloric obstruction. Ulcer, cicatrix, and malignant disease were, of course, by far the most frequent. In many cases an element of spasm was added, and doubtless cases occurred in which there was pyloric spasm alone, apart from any organic narrowing. Lauder Brunton had drawn attention to a group of cases in which pyloric spasm was associated with, and formed one of the symptoms of, an attack of migraine. The chief symptoms of pyloric obstruction were dilatations of the stomach, ptosis of the organ, and in many cases peristaltic waves. If the latter were present it was proof that there was no atony of the stomach wall. An atonic condition was most likely to supervene either when there was a long-continued history of simple stricture, or in malignant cases of short duration associated with much wasting. In some cases a definite pyloric tumour could be felt, and in these the diagnosis of pyloric stenosis was obvious.

Congenital pyloric narrowing has not hitherto had any definite clinical position given to it, although it has been suggested that it may occur. The speaker's attention had been drawn to the subject through reading of the cases reported by Maylard, of Glasgow. Historically, the earliest references to the condition were in the papers published by Landerer in 1879, and

Maier in 1885. The former reported 10, and the latter 31 examples. In these cases there was simply a narrowing of the pylorus, and Maier differentiated two groups of cases—(1) the simple form, and (2) the combined form, in which there was an associated hypertrophy of the muscular coat. Of late years congenital hypertrophic stenosis of the pylorus in infants had aroused a great deal of attention, and its clinical symptoms, thanks to the number of papers on the subject which had been published, were now so well known as not to require mention, and, indeed, were so characteristic that it was a wonder the disease had passed so long unrecognised. He noted that there was little unanimity of opinion as to the treatment of this disease. Some physicians (*e.g.*, Pfaundler) thought operation to be unnecessary; others believed almost every case ought to be treated surgically. He thought those who had opportunities of seeing many infants ought to be on the look-out for a simple form of stenosis, as well as the hypertrophic type. At present there was no definite explanation of the occurrence of simple stenosis in the adult.

He read notes of three cases in adults which were believed to be of this nature; all had been dealt with surgically. An important point in the diagnosis was the history, which extended back into childhood. (Owing to the exigencies of time, Dr. Russell was compelled to greatly curtail the latter part of his communication.)

Mr. **CAIRD** said that the difficulty was to prove that such cases actually were congenital. The histories were not reliable as to the events of infancy unless they were obtained from the parents, as well as from the patients themselves.

Dr. **JOHN THOMSON** agreed with Mr. Caird, and stated that, although he had looked out for years for simple stenosis in infants he had never seen a case; this was also the experience of others.

Mr. **MAYLARD** believed that these cases did exist. He dwelt on the variability of the symptoms, and said they were often diagnosed as ulcer, etc., the true condition being only detected at the time of operation. Formerly he advocated gastrojejunostomy; now he considered pyloroplasty much better.

Dr. **DAWSON TURNER** read a paper on the

TREATMENT OF ANEURYSM BY ELECTROLYSIS.

One could not fail, he said, to be struck by the diversity of methods which had been recommended. Ciniselli inserted one electrode into the aneurysm and reversed the direction of the current every five minutes or so. The late Mr. John Duncan, who gave so much attention to electrolysis, inserted both poles, and latterly adopted the expedient of allowing the point of the positive pole to play against the wall of the aneurysm and cauterised it here and there. The negative pole caused a great deal of frothing, from the gas which was set free, the positive pole caused a firm coagulum of albumin. Moore and Corradi employed the positive pole, using electrodes of gold, platinum, silver, copper, zinc, etc., and passing a current of 50 m.a. for an hour. Dr. Turner then demonstrated the effects of electrodes of various metals on serum, by means of a projection lantern. In all cases the negative pole presented a very striking appearance by reason of the quantities of gas given off. The appearances at the positive pole varied much according to the metal used. With gold, silver, platinum, the serum appeared to undergo little change; when copper, and particularly zinc, was employed, a firm coagulum of albumin was quickly developed. Several conclusions were drawn from the experiments. In the first place, Dr. Turner thought that, as it was ordinarily practised, electrolysis was of very little value indeed. Secondly, apparently the fear of gas bubbles entering the circulation was nothing but a bogey. As carried out in many cases quantities of gas were set free, and apparently did no harm. Thirdly, the most efficient means of producing a coagulum was by using zinc as the positive pole. With the normal 50 m.a., for an hour only, 5 centigrammes of the metal were dissolved. A firm coagulum of albuminate of zinc was formed. It was probably most likely to do good when it was combined with the introduction of a coil of wire into the aneurysm. The wire so introduced might be zinc, and employed as a terminal. It would be very desirable to try and ascertain whether the albuminate of zinc so deposited favoured the formation of fibrin clot which was capable of organisation, and also to discover the action of the zinc electrode on whole blood, not serum.

Mr. **CAIRD** said that the surgical treatment of large aneurysms which were inoperable by the usual methods was extremely disheartening. He was not impressed by the benefits of electrolysis, and thought that much of the good was due to the scratching of the aneurysm walls by the electrodes, just as had been found by McEwen in using needles.

Dr. **J. S. FRASER** read a paper on "Chronic Inflammatory Œdema of the Submucous Tissue of the Nose." Instead of delivering his paper *in extenso*, he demonstrated a number of microscopic preparations of the turbinals. These specimens showed that chronic hypertrophy of the turbinals was due to œdema; in one specimen appearances suggestive of thrombosis of a vein were present, suggesting that this might be the cause of the œdema. A strong point was made of the similarity in structure of the œdematous tissue and the ordinary mucous polypus. The opinion was expressed that a polypus was nothing more than an exaggeration of the condition found in hypertrophy. When the hypertrophy affected the middle turbinal the œdematous tissue from the action of gravity came to hang down more and more and gradually formed a polypus. When the lower turbinal was affected the force of gravity did not come into play in the same way, the œdematous tissue rested on the floor of the nose, and consequently there was no polypus. Polypus was rare compared with hypertrophy; and it was never met with in children, in whom hypertrophy is so common. This, in Dr. Fraser's opinion, showed that a long period was needed for the development of a polypus.

Dr. **LOGAN TURNER** and the **PRESIDENT** discussed the communication.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, MAY 29TH, 1908.

Sir A. V. MACAN, and subsequently the **PRESIDENT**, in the Chair.

TWO UTERI REMOVED FOR ADENO-CARCINOMA OF THE BODY.

Dr. **GIBSON** exhibited specimens as above. The first was from a young woman, æt. 26, who had been married for one year, and had not yet become pregnant. She only complained of irregular uterine hæmorrhage. The uterus was apparently quite normal, but examination of the curettings revealed adeno-carcinoma. In the second case the woman, æt. 42, had had three children. This patient, like the first, only complained of irregular hæmorrhage, but the case was more marked than the first, as she had an enlarged uterus. The diagnosis was made from the curettings. Except for the attacks of hæmorrhage every two or three weeks, both women were in apparently perfect health. He brought the specimens forward as showing the importance of curetting in all such cases, and of the absolute necessity of routine examination of the curettage.

Dr. **HOLMES** said that 26 was an early age at which to find carcinoma, although he had known a case at 18. He agreed as to the importance of routine examination in all cases where curetting was done.

The **CHAIRMAN** said the youngest case of carcinoma he had seen was at 27, and if it occurred as early as Dr. Holmes said—18—it might occur at any time.

DERMOID TUMOURS.

Dr. **HORNE** exhibited two specimens of dermoid tumours which had occurred in one patient, a condition he had not met before. The girl was suffering severe pain eight or ten days before menstruation. Last October menstruation ceased, and the pain lessened, and she came to him to know what was wrong. By vaginal examination he found one tumour in front of the uterus; uterus was pushed to the right, and through the fornix a certain amount of bony hardness was found. On going into the posterior *cul-de-sac,* he found it occupied by a semi-resistant tumour, which felt in size like an extra-uterine pregnancy, but in one part there was a hard nodule. At the operation he found the tumour in front completely covered by the omentum, which passed over it and was adherent to the bladder. He then came on a slight pedicle, and in trying to keep close to the tumour some of the contents—typical yellow fluid—escaped. He removed the tumour in front, and shelled out the second from behind the uterus.

Dr. **Rowlette** asked if Dr. Horne had established any connection between the second tumour and the ovary.

The **Chairman** said it was a wise thing not to run any risks with dermoid cysts, as their contents were sometimes very septic.

Dr. **Horne**, in reply, said the second tumour lay altogether behind the peritoneum, and he could find no trace of the ovary. On account of the escaping fluid he provided drainage into the vagina, and packed the cavity with iodoform gauze. The case had run a most satisfactory course

ECTOPIC GESTATION, WITH OVARIAN CYST.

Sir A. V. **Macan** exhibited a specimen of ectopic gestation, with ovarian cyst. The patient came to him in July last, when he found a tender tumour behind the uterus slightly to the left side. In November he enucleated a small fibroid that had been undergoing calcareous degeneration, and he removed the left ovary, which was degenerated. She made a good recovery, and went home in December apparently quite well. About the middle of May she came to him again, miserably thin and pale. She had been in bed for a month, and had had a red discharge for three weeks, as well as severe abdominal pains. He examined her and found the uterus dislocated to the left, and a large elastic swelling filling the right side of the pelvis. The whole abdomen was very tender. He could make no other diagnosis than that of extra-uterine fœtation. He operated last Monday, and found considerable adhesions. There was hardly any blood in the peritoneum. He enucleated a large lump in the right side of the pelvis which he thought was part of the fœtation. Careful examination showed a rupture in the tube.

Dr. **FitzGibbon** said the specimen was particularly interesting as showing the rapidity with which the ovary could grow, and the possibility of growth at that rate being malignant.

THE OBSTETRICAL REPORT OF THE ROTUNDA HOSPITAL, 1907-1908.

The obstetrical report of the Master of the Rotunda Hospital for 1907-1908 was read by Dr. W. Bell.

Dr. **Horne** said they were delighted to see the improvement in the morbidity, though he would prefer to see some one definite method of calculating it adopted. The mortality was also extremely good, yet two deaths out of nine eclampsia cases seemed high in view of present-day methods.

Dr. **Gibson** had great pleasure in congratulating the Master of the Rotunda Hospital and his assistants on the large amount of work done. He regretted that he had not yet had an opportunity of reading the report, as a copy had not been sent to him. Dr. Bell had drawn special attention to the fact that one woman, for whom pubiotomy was necessary on a former labour, had now delivered herself spontaneously. This was, of course, one of the greatest advantages of pubiotomy, that they could give the patient every opportunity of delivering herself, and only perform the operation when it is indicated.

Dr. **FitzGibbon** said that when he was at the Rotunda cases of venereal disease in pregnancy were looked upon with abhorrence, and a large percentage of them died of septic infection afterwards. It was interesting, and apparently inexplicable, that there had never been a death after childbirth in the Lock Hospital, which was saturated with venereal disease, yet in the Rotunda, where there were the very best conditions, deaths occurred. In a recently reported autopsy the results of a previous pubiotomy were examined, and the bone showed no attempt at osseous union which might explain some cases of easy delivery after pubiotomy, as the fibrous union gave greater space.

Sir **Arthur** V. **Macan** said that the great majority of obstetricians abroad recognised 38° C. as the limit of morbidity, and he thought they should adopt it unless there was some very great objection to it. Statistics on different standards were useless, and they must use a standard that others understood if they were to compare the Rotunda with other places. He was convinced of the ease and simplicity of pubiotomy, but it had been shown that serious accidents might occur in the hands of the most skilled men, and, therefore, he could not consider the operation one to put before a man in ordinary country practice as the most suitable and certain. At the same time, it was better to perform the operation in an emergency than to let the woman die without any attempt to save her. He thought that cases of convulsions should not be allowed to go on where the sight was already affected; everything—even Cæsarean section—should be done. He thought that the case of death from shock immediately after the removal of adherent placenta was worthy of more detail, as the operation was the most dangerous one in midwifery.

THE GYNÆCOLOGICAL REPORT OF THE ROTUNDA HOSPITAL, 1905-1907.

Dr. A. **Holmes** read the above for the Master of the Rotunda. The Gynæcological Report of the Rotunda Hospital covers two years, beginning November 1st, 1905, and ending October 31st, 1907, and deals only with those cases in which operative measures were undertaken. In many instances several operations were necessary, and were performed at the same time. Each operation is counted under its own heading. The number of patients admitted to the hospital during the two years amounted to 981, of these 110 were cases where no operation was performed or operation was refused. The total number of operations performed comes to 1,153, of which 468 come under the heading of curettage. Operative measures for rectifying backward displacements of the uterus were undertaken in 94 cases. The Alexander-Adams' method was elected on five occasions, vaginal fixation twenty-three, and ventro-suspension on the remaining sixty-six. Myomectomy was performed whenever possible, and was adopted on fourteen occasions. Hysterotomy was necessary once for overcoming the symptoms associated with an irreducible retroverted gravid uterus. Hysterectomy was performed in all sixty-seven times, malignancy being the indication in twenty. The mortality following upon extirpation of the uterus for malignancy is represented by seven, showing a percentage of 35. Fibroid condition of the uterus accounted for thirty-seven of the other cases; pyosalpinx, intraligamentous cysts and severe hæmorrhage the remainder. Forty ovariotomies are recorded, with a mortality of five, in two of which malignancy was the indication for operation, and probably in a third case, the pathological findings not being definite. The two other cases were in a hopeless condition of sepsis on admission. Many operations in minor gynæcology were performed for repair of torn perinæum, cervix, etc. The total mortality is represented by twenty-one. Twelve deaths occurred in cancerous patients, two followed hysterectomy for fibroid condition—one of which cases succumbed to congestion of the lungs, and the other to shock. A pyosalpinx which ruptured during removal accounted for another. Two women died who suffered from irreducible retroverted gravid uteri; both were moribund when accouchement *forcé* was resorted to. Another death occurred in a woman pregnant four months, and with an ovarian cyst whose pedicle was twisted and gangrenous. Cerebral symptoms pointing to tubercular meningitis arose in a patient who was suffering from ovarian cyst associated with a very high temperature, and proved fatal. The remaining two cases died before operation—one from peritonitis, the other of pneumonia.

Dr. **Seymour Stritch**, adverting to the question of mortality, said that there had not been a death in the Lock Hospital of any sort following confinement during the last twenty-eight years, and only one death occurred in the London Lock Hospital, he was informed, in twenty-five years. In the Dublin Lock Hospital there were about twenty cases of delivery annually. Douching was constantly done. An account of these cases would be found in THE MEDICAL PRESS AND CIRCULAR for July 4th, 1906.

Dr. ASHE said that shortening the round ligaments, in his experience, had been most unsatisfactory, and he would like to know if anything had afterwards been heard about the cases operated on.

Dr. KIRKPATRICK suggested the inclusion of a statistical table in connection with the administration of anæsthetics as a matter of considerable importance which would make a valuable addition to both reports.

Dr. BELL said that the measurements of the true conjugate of the patient who had delivered herself after pubiotomy were 7 cm. last year, and 8 cm. this year. No one who has had much practice with Skutsch's pelvimeter will believe that such a discrepancy could be possible, and the fact remained that the woman delivered herself this year in six hours. Last year she was in labour forty-two and a half hours, with the head balloting freely above the pelvic brim, when forceps were applied. They failed to fix the head in the brim. Three hours later pubiotomy was performed. Walcher's position was tried for one and a half hours without success before pubiotomy was performed.

Dr. HASTINGS TWEEDY said he did not think any apology was necessary for the method of ascertaining morbidity which had been adopted at the Rotunda. Reference had been made to the Queen Charlotte Hospital report, where a morbidity of 20 per cent. was shown when estimated by the rigid methods adopted at that institution; and yet, when this morbidity was calculated by the rules laid down by the British Medical Association and by those which obtain at the Rotunda, it showed a marked decrease. It was unfortunate that the British Medical Association and Rotunda estimations of morbidity in the Queen Charlotte Hospital report were estimated from only a small number of their cases—*i.e.*, 300 British Medical Association and 89 Rotunda. Needless to say it is impossible to draw any comparison between their percentage morbidities, as the different calculations did not deal with the same number of cases. We at the Rotunda could easily show a hundred consecutive cases without any morbidity. Thirty-eight degrees was a purely arbitrary line, and it was futile to take temperature in the axilla and compare them with those taken in the mouth or rectum. The British Medical Association suggested that the thermometer be placed in the mouth; the temperature be taken twice daily—at 8 a.m. and 5 p.m.; and in these suggestions they were far ahead of any plan generally adopted on the Continent. A greater number of temperatures would be found in four-hourly records than in bi-daily records. He was not interested in these rises of temperature save as an indication of disease, and it was misleading to schedule every patient as diseased (morbid) who showed some slight transitory rise. What we really want are statistics of the health of the various hospitals, and to this end the plan of the British Medical Association is worthy of much wider recognition than it has yet received. Two women on whom he performed pubiotomy last year had since delivered themselves naturally. Those cases had been carefully measured by Skutsch's pelvimeter, had had the head balloting above the brim of the pelvis for several hours before operative interference was adopted, and had shown marked pelvic contractions, measurements of which will be seen by referring to the report. One of these showed a marked increase in the pelvic measurements when examined before the birth of the second child. In conclusion, he expressed his admiration of the way in which the work of the reports had been done by Dr. Bell and Dr. Holmes. The former had omitted the reading of the paragraph referring to himself and Dr. Holmes, an omission which Dr. Tweedy supplied.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 14th, 1908.

HYPERHYDROSIS OF THE FEET.

FOR the treatment of this troublesome affection, Hebra proposed a treatment which he considered as heroic. He enveloped the foot with a plaster composed of equal parts of diachylon and linseed oil. After 12 hours the dressing was removed, the feet dried, and the application renewed, and so on for 10 or 12 days. At the end of that time the plaster is replaced by some absorbent powder.

Kaposi recommends the employment of naphthol in lotions morning and evening:—

Naphthol, 5,
Glycerine, 10,
Proof spirit, 100,

and powdered with—

Naphthol, 3,
Starch, 100.

Salicylic acid has been employed by Broca. After rubbing the feet with a spirit lotion, he employs the following powder:—

Salicylic acid, 3,
Starch, 10,
Fuller's earth, 87.

Or,

Powdered alum, 45,
Salicylic acid, 5.

Perchloride of iron has been used with advantage.

Glycerine, 2 dr.
Perchl. of iron, 1 oz.
Ess. of bergamot, 20 drops.

During two days the feet are bathed in some astringent decoction, and on the third day the above mixture is painted on the feet morning and evening.

In the German army chromic acid is the current treatment.

A complete cure is effected in 42 per cent. of the cases, improvement in 50 per cent., and only 8 per cent. are rebellious to the treatment.

The chromic acid is employed in solution (5 to 10 per cent.), and rubbed on the soles of the feet and between the toes with a piece of cotton wool after the feet have been thoroughly washed. The operation is renewed at an interval of a week or fortnight.

STICKING PLASTER.

M. Kogaul indicates a simple and practical method of applying adhesive plaster without heating it over steam or fire. It is sufficient to pour a little benzine into a plate, and pass the straps through it before applying them. To remove the plaster a plug of cotton wet with the benzine is passed over it, when it peels off with the greatest facility.

CHRONIC APPENDICITIS IN CHILDREN.

Appendicitis, frequent in children, is essentially, says Prof. Comby, a chronic affection. How it commences is unknown, and in this it resembles adenoid vegetations, hypertrophy of the tonsils or ganglions, and all other morbid affections of slow and prolonged development.

When one is put on the track of appendicitis by such symptoms as local pain, nausea, vomiting, etc., it has already a long time existed, having progressed insidiously in the midst of the vaguest and most deceptive symptomatology.

When an acute attack has suddenly appeared, it is regarded as one of those accidents that could not have been foreseen; but acute appendicitis is only an episode of the chronic form.

In many cases the cause of chronic appendicitis in children escapes notice; the patients are well nourished, never suffer from troubles of digestion, never had an attack of enteritis, and seem to have always enjoyed good health. Here heredity, lymphatism, arthritism, might be invoked as exciting causes.

In another class of cases may be noticed rhino-pharyngeal manifestations, adenoid vegetations, with or without otitis. These children have a weak throat, are easily seized with inflammation of the tonsils after the slighest cold or an attack of grippe, accompanied by cervical adenitis. After one or several of these attacks, the first symptoms of chronic appendicitis appear.

Others have suffered from attacks of gastro-enteritis or entero-colitis in their infancy. M. Comby observed a large number of children who were treated first for entero-colitis and in whom the malady terminated in chronic appendicitis. The coincidence of these two maladies is very frequent in children.

Among the infectious maladies, there is one which plays a principal *rôle* in the ætiology of appendicitis. Influenza presents a predilection for the lymphatic apparatus, and determines engorgement of the ganglions. The appendix might be assimilated to a ganglion.

Next in order comes typhoid fever, measles, scarlatina, mumps, and generally all infectious maladies which in children affect specially the lymphatic system. Abuse of certain foods, meat, raw vegetables, and all indigestible foods play an important *rôle*, by irritating the intestines and provoking abnormal fermentations.

Rare in infancy, chronic appendicitis becomes more and more frequent as the child advances in age; it is common between the ages of 5 to 15, and may be prolonged to the adult age.

The symptomatic tableau of chronic appendicitis is exceedingly complex. Sometimes the latent affection is mirrored on the physiognomy of the child, which attracts attention, at other times none of the features betray the cause; on the contrary, the face has all the appearance of health. In general, however, the children are pale, complexion waxy, eyes sunken, face emaciated. At the same time the whole body participates more or less in this wasting, the limbs are slight, the abdomen hollow, the ribs protuberant, etc. This external habitus is seen, above all, in children who have suffered from enteritis or dyspepsia.

The patient has little or no appetite, he eats by force, or his appetite is capricious and irregular; good to-day, bad to-morrow.

Some children, on the contrary, eat ravenously, and too much, they digest with difficulty, are swelled after meals, and present signs of dilatation of the stomach, and flatulent dyspepsia. With this dyspeptic condition constipation almost always coincides, while others suffer from diarrhœa, or from diarrhœa and constipation alternately.

Several present a saburral condition of the tongue, with fœtidity of the breath, especially in the morning They are subject to gastric disturbance. All these digestive troubles are vague, ill-defined, and of difficult interpretation. They are generally considered as symptoms of ordinary indigestion.

GERMANY.

Berlin, June 14th, 1908.

At the Hufeland Society, Hr. Kraus showed a case of

BRONCHIAL CALCULUS.

The patient was a man between 40 and 50, whose father had died of phthisis. He himself had previously suffered from cardiac trouble. For six years he had suffered from cough, night sweats, and emaciation. More recently there had been paroxysmal attacks of coughing, with severe pain in the shoulder region, burning in the trachea, with vomiting at the height of the attack. There was also expectoration of small, linseed-shaped, calculi with prickly processes; after this improvement took place. The sputum contained bacilli. Röntgen illumination showed the outlines of calculi disseminated through the chest. Cases of expectoration of calculi had very rarely been described.

Hr. Kraus also showed a lady, in good health, who was the possessor of cervical ribs, as shown by the X-rays. The ribs were causing some inconvenience, however, as by pressure on the brachial plexus, pain was caused in the shoulder and arm of the side affected. As in other cases the pain was a long time before it appeared. It would be easy to give relief by operation.

Hr. Senator said he had frequently found cervical ribs, as, in order to discover any possible cervical glands, he was in the habit of palpating the side of the neck in all cases.

Hr. Kraus next showed a case of

ECHINOCOCCUS.

It was remarkable that it had started from the posterior margin of the liver, and the diagnosis was difficult as the situation was unusual. It gave the operator a good deal of trouble to arrest the hæmorrhage.

Hr. Mosse showed preparations from a case of

LYMPHÆMIC CIRRHOSIS OF THE LIVER.

The patient was first examined three years ago, and a diagnosis was then made of chronic lymphatic leucæmia. In 1905, and later in 1906, the X-rays were applied. The result was that the lymph tumours and the spleen were reduced in size, the blood also improved. In January, 1907, there was a good deal of ascites. As displacement of the portal vein was supposed to have taken place through enlargement of the lymph glands the treatment was renewed. The patient then left the hospital. The autopsy showed chronic peritonitis, no enlargement of the lymph glands of the abdomen whatever, but excessive cirrhosis of the liver. This and the peritonitis might be a result of the X-ray treatment. The cirrhosis of the liver and the leucæmia might here be accidental concomitants, but cases of the kind were described by other authors.

Hr. Kraus did not think that the liver disease was caused by the Röntgen treatment. Cirrhosis of the liver often occurred with pseudo-leucæmia.

DEMONSTRATION OF PANCREATIC DISEASE.

Hr. Ewald showed some microscopic preparations, pointing out that they showed the action of the pancreatic secretion. This digested the nuclei of muscles. Where such were recognisable in the fæces the pancreas could not have been acting. He showed small particles of flesh which had been swallowed by the patient wrapped up in gauze, as these were quickly found in the fæces the examination was rendered more easy.

Hr. Strauss spoke on

PROCTITIS SPHINCTERICA.

He said the disease was characterised by redness and swelling in the region of the sphincter, with tendency to excoriations and ulcerations, and frequently set up considerable disturbances. It was often overlooked if the rectal speculum was not made use of. Not infrequently a nervous spasm of the rectum was diagnosed, which on more careful examination proved to be sphincteric proctitis. Considerable hæmorrhages were also not rare, so that one thought of carcinoma. As regarded treatment, besides sitz baths and suppositories, applications of silver nitrate through the speculum were called for, or injections or ointments applied through a syringe. The speaker had become more backward in making a diagnosis of rectal spasm the more his experience had increased in the use of the rectal speculum.

AUSTRIA.

Vienna, June 14th, 1908.

TALLOW CANDLE IN BLADDER.

At the Gesellschaft der Aertze, Lenk showed the remains of a tallow candle which he had removed from the bladder by what he called a new method, and which we may now call "Lenk's method." For some time past the patient had suffered from severe attacks of hæmaturia and cystitis, which persisted in spite of heroic treatment. The cystoscope revealed ulcerous cystitis in the lower part of the bladder with an encrusted foreign body. When the bladder was filled the foreign body floated and sank when it was emptied. Further examination proved it to be stearin, but how was it to be removed—by the lithotrite or section. Owing to ulceration the sectio alta was entertained, but the cystitis was dreaded.

After consultation it was decided to dissolve the foreign body if possible by means of benzine. The first step was to inject 13.0 cubic centimetres of sterilised water into the bladder which floated the candle; after this 60 cubic cm. of benzine was injected, which remained on the surface of the water in contact with the stearine. This device protected the lower ulcerated part of the organ, and prevented further aggravation of the cystitis. The benzine was only allowed to remain 20 seconds, and was then drawn off, at the same time washing out the bladder well with sterilised water. After the action of the benzine the stearine, with the heat of the body, commenced to break up, and was passed with the urine as a thick oily substance. Five more injections of benzine and washings were applied, but none of these exceeded 20 seconds before the oily discharge ceased. The next difficulty was the removal of the cotton wick, which was done with the lithotrite. Mastubation was the original cause of the accident.

IMPERFECT VISION AND PREGNANCY.

Meissner presented a woman in pregnancy three months, with greatly impaired vision. According to her history six years ago she suffered from a severe attack of neuritis optica, the result of syphilis. After this illness her eyesight remained fairly good for two years till she became pregnant, when her sight was greatly impaired. After the confinement her vision improved, but never came up to the clearness it was before the confinement. Later she again became pregnant with the same result, improving after the confinement, but still worse than before it.

She is now three months gone in the present pregnancy with the eyesight again impaired, which she thinks would be better if the pregnancy could be ended. The right eye can distinguish fingers at 3 metres or 9 ft. 9 in., the left at 3¼ metres. The ophthalmoscope revealed signs of neuritis optica in both eyes with regular and irregular astigmatism. Vision is concentrically limited, and the only colour distinguished red. No trace of syphilis to be found now, and no albumin in the urine; notwithstanding iodide and syphilitic treatment was adopted without success, indeed the vision became rapidly worse during the administration of the drug.

There is no doubt in this case that the pregnancy is the cause of the reduced vision which raises the important question of inducing premature labour as suggested.

Königstein said he had had the opportunity of examining this patient a few weeks ago, and was impressed with the idea of inducing abortion, but one must always take into account the amount of hysteria present in these cases which the other functions verified.

Bäringer thought if no simulation could support the case it was grave, but his own opinion from the history of the case was that no attempt at abortion should be made. He believed that the woman's danger would be greatly increased by such interference.

Hirschl thought that Meissner should have treated the case with mercury, as iodide alone was not proper anti-syphilitic treatment.

Hochenegg said he sympathised very much with the patient's grief concerning her blindness, and from the history of the case vision was very much disturbed. As a cause of this defect he should remind his hearers of the recent facts noted by French authors as well as Erdmann and Stumme, who have all found changes in the hypophysis. Meixner reminded Hochenegg that the characteristic hemianopsia which is usually associated with the disease of hypophysis was not present in this case.

Teleky said that in his long practice he had never met with a case where the ætiology was due to pregnancy pure and simple, but with albuminuria he had often met with retinitis.

Stejskal thought that atrophy of the optic nerve might be present, and that the organic changes occurring in the gravid state might be due to exostosis or periostitis in the ocular orbit. Such exostosis during pregnancy is not an uncommon associate.

CONTINENTAL HEALTH RESORTS.

AIX-LES-BAINS.

A VISIT to Aix-les-Bains (that ancient thermal resort famous alike for its treatment, its gaiety, and the delightful character of its surroundings) ought to form part of the curriculum of medical study. It is, so to speak, the mother of thermal stations, its early history going back to the dawn of Christianity, and it has served as a model for similar establishments all over the world. Not every spot where hot springs are available can command the lovely scenery and the bright genial climate of Savoy, which, by the way, was Italian territory until 1860, when it was annexed to France after a referendum of the inhabitants. It is a remarkably fertile soil, every inch of which is diligently cultivated by a thrifty, hard-working population.

The facilities for entertainment and promenades in and around Aix are almost unrivalled. The country roads are kept as only French roads are kept, and they provide miles and miles of leafy avenues which are delightful on foot or on wheels, or viewed from the cushioned indolence of the local fiacre, which again is a marvel of primness and comfort Then, too, there are two Casinos, probably the largest, and certainly among the most beautiful, in Europe, where we are treated to theatrical representations by metropolitan troupes, open-air opera, orchestral and vocal concerts, not to speak of gaming rooms, attractive lounges and gardens, in which Art and Nature have joined hands to produce most striking effects. The gilded saloons are nightly thronged by a cosmopolitan assembly of all nationalities and of all ages, clad in the height of fashion, a truly democratic institution, where social differences seem to be obliterated in the pursuit of pleasure.

But we must not lose sight of the fact, especially in a medical journal, that Aix-les-Bains is essentially a thermal station, whither thirty or forty thousand specimens of suffering humanity find their way every year for the purpose of undergoing a course of treatment. These include the victims of rheumatism, gout and arthritic states in general, obesity, neurasthenia, gouty eczema, varicosity, and stiff joints, the result of traumatisms or chronic inflammation. The best testimony to the usefulness of the treatment is that its reputation has been maintained for about twenty centuries. Mere fashion would long since have spent its force, so we are compelled to believe in the curative effects, if not of the waters *per se*, at any rate of the mode or rather modes—for they seem to be innumerable in their variety—in which they are applied. We may remind our readers that the Aix water issues at a temperature of about 110° F. to the tune of a million gallons a day, its principal component being sulphur in the form of sulphuretted hydrogen and *baragene*, an unctuous substance that greatly facilitates massage.

The bathing establishment, which is on a palatial scale, is the property of the State, which turns it to national account by according its benefits to the sick poor and underpaid employees at a nominal cost, or even free of charge. Even "paying guests" find the charges very reasonable, varying, as they do, from a franc per bath (douche-massage) in the older part to 2f. 50c. and 4f. in the more luxuriously installed departments. It is hardly necessary to add that, apart from the Aix treatment proper, which is known all over the world as douche-massage, every variety of hydropathic treatment is available, including the treatment of diseases peculiar to women, of intestinal affections, not to speak of the throat, nose and air passages. It is quite a department of therapeutics in itself, and must require no small experience to master in all its details. Every year witnesses some additions in deference to the representations of the local medical society, and, thanks to the kindness of Mr. Durand-Desmond, the director of the establishment, and of Mr. Marillet, the assistant director, we have been enabled to inspect some of the more recent improvements which comprise an installation for intestinal irrigation, special douches for women, especially the so-called "marine douche" (vaginal douche taken in the ordinary mineral water bath), and a very elaborate horizontal douche-massage table for patients who are too weak or too infirm to avail themselves of the stool that is usually employed.

Municipal enterprise is shown in the tarring of the streets, a matter largely due to the personal initiative of M. Mottet, the popular and quasi-permanent Mayor of Aix. The streets present a smooth surface free from dust—a point of immense importance in view of the hundreds of powerful cars that daily pass through or arrive at Aix every day during the season. The tarring is carried some distance out into the country, so that *promeneurs* can take their walks abroad without being smothered.

We may mention, too, that, in order to attract medical men hither, and induce them to become personally acquainted with the resources of the bathing establishment, they and their families are accorded the treatment free of charge, and on presentation of their cards they are admitted to the casinos and other entertainments.

There is a charming public park, on one side of which is a well-installed Zander Institute, under the direction of Dr. Guyenot. Aix is half-buried in verdure, and the air is redolent of the perfume of acacias, magnolias, polonias, and other scented flowering trees. Hotel accommodation at Aix is excellent, the establishments most favoured by English folk being the Grand Hotel d'Albion (very select and comfortable), the Hotel Bernascon, and the Hotel Splendide.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Chair of Clinical Surgery, University of Edinburgh.—The King has been pleased, on the recommendation of the Secretary for Scotland, to approve of the appointment of Mr. F. M. Caird as Regius Professor of Clinical Surgery in the University of Edinburgh. Professor Caird, who graduated in 1877, is one of the best known surgeons in Edinburgh, and is extremely popular, both personally and as a teacher. The branch of surgery in which, perhaps, he particularly excels is abdominal work generally, and he was one of the first surgeons to take full advantage of and apply modern methods to the operative surgery of the abdomen. As an undergraduate he was trained by Lister, and witnessed the revolution in surgical science and practice which resulted from the labours of his teacher. He subsequently studied pathology under von Recklinghausen, and taught anatomy under Dr. (now Professor) Cossar Ewart. He then acted as assistant to Mr. Chiene, and in 1886 was elected assistant surgeon to the Royal Infirmary. He lectured on systematic surgery in the extra-mural school of medicine for nearly twenty years, and his class was regarded by the students as one of the best in Edinburgh; its popularity is evidenced by the fact that the average attendance throughout these years was 106. In 1900 Mr. Caird became a full surgeon to the Infirmary and began to lecture on clinical surgery. The appointment, which was announced in the beginning of last week, has been received with very general satisfaction.

Chair of Medicine, University of Glasgow.—The King has been pleased, on the recommendation of the Secretary for Scotland, to approve of the appointment of Professor Samson Gemmell as Professor of the Practice of Medicine in the University of Glasgow. Dr. Gemmell graduated in 1872, and for a time acted as assistant to the late Prof. Sir William Gairdner. From 1873 to 1876 he acted as resident physician at the Glasgow Fever Hospital, and in 1887 he was appointed physician to the Royal Infirmary. Since 1892 he has been physician at the Western Infirmary, Glasgow. In 1900, on the appointment of Sir Thomas McCall Anderson, then Professor of Clinical Medicine, to the Chair of Practice of Physic, he was appointed to the former chair. In his new post, therefore, he has again succeeded the late Prof. McCall Anderson.

Sir Henry Littlejohn's Retirement.—The Local Government Board, in a letter accepting, with deep regret, Sir Henry Littlejohn's resignation, refer to his work in most appreciative terms. They recall the fact that long as has been Sir Henry's period of service as Medical Officer of Health for Edinburgh, his connection with the board has been longer still, dating, as it does, from 1859, when as a Commissioner, Dr. Littlejohn investigated the epidemic of Asiatic cholera then visiting the country. The appreciation of his services as a Commissioner from time to time led the Board in 1873 to attach Dr. Littlejohn permanently to its staff. The value of this unique record of half a century's strenuous work cannot well be over estimated. The terms of the appreciation are to be officially communicated to the Secretary for Scotland for his information.

Fatal Assault on a Medical Man.—A lamentable occurrence is reported from Ardrishaig, whereby Dr. Duncan Shaw Morrison lost his life. It seems that the deceased gentleman left Loch Gilphead for home about 11 o'clock on Wednesday evening, and on the way was overtaken by two men who have been working in the district for some time. What led to the assault is not yet known, but a dispute arose, with the result that Dr. Morrison was knocked down. Almost immediately afterwards two cyclists came on the scene and challenged the assailants. Seeing the state of matters, with Dr. Morrison lying on the roadside bleeding profusely and apparently unconscious, they compelled the two men to accompany them to the nearest village, where they were handed over to the police. Meanwhile help was sent to Dr. Morrison, but by the time it arrived the victim of the assault was *in extremis*, and expired a few minutes later. The deceased was about fifty years of age, and was unmarried. The prisoners were brought before Sheriff Penney on the capital charge, and after emitting a declaration were committed for further examination.

Chancellorship of Glasgow University.—The new Chancellor, Lord Rosebery, was formally installed in office on June 12th, additional interest being lent to the occasion by the fact that the first duty of the new Chancellor was to confer the Doctorate of Laws on the Duke of Argyll, Lord Elgin, and Lord Newlands. Following upon his induction to the office of Chancellor, Lord Rosebery delivered an eloquent address, contrasting the spirit and work of individual Universities, and speaking especially of the self-reliance which the Scottish Universities fostered in their students. The proceedings were brought to a close by a luncheon party, at which the Chancellor, the Duke of Argyll, and Lord Elgin gave addresses.

Memorial to the Late Professor Annandale.—A sum of £231 15s. has now been subscribed towards this object, leaving £168 5s. still to be found before the sum of £400, at which the Committee aim, is raised.

Mr. F. H. A. Marshall, Assistant to the Professor of Physiology, and Lecturer on the Physiology of Reproduction in the University of Edinburgh, has been appointed to a newly-instituted Lectureship in Agricultural Physiology in the University of Cambridge.

BELFAST.

Meat, Milk, and Tubercle.—At the last monthly meeting of the Corporation, a statement was made by the Chairman of the Public Health Committee, Dr. King-Kerr, regarding the occurrence of tubercle in cattle. He said that, of 3,452 milch cows examined by their veterinarian, only one was found affected with tubercle, and of 27,446 cattle slaughtered in the city abbatoir, only 384 showed tubercle, or about one animal in 70. For three months Professor Symmers had been making elaborate examinations of milk from city dairies, but had never found tubercle bacilli in any sample. In discussing these figures it was made clear that in the case of the milch cows the tuberculin test had not been applied.

Typhoid Fever.—In spite of all efforts to stop the consumption of cockles—the supposed source of typhoid infection in Belfast—there is no abatement in the number of cases, but rather the reverse. Last month there were notified 29 cases of typhoid and 14 of "simple continued fever," which may be counted as typhoid, making 43 cases in all. Apart from this, the general health of the city shows distinct improvement.

AMENITIES OF HOSPITAL LIFE.—Much interest and amusement have been roused in medical circles in Belfast by the announcement of the engagement of a prominent surgeon, supposed to be a confirmed bachelor, to the matron of one of the hospitals to whose staff he belongs. The special interest lies in the fact that it is just a year since his surgical colleague on the staff married the late matron, and it is felt that the Board of Management have a responsible task before them in selecting the next, as there are still several bachelors on the staff!

LETTERS TO THE EDITOR.

THE STUDY OF TWINS AND DOUBLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly allow me once again to appeal to your readers for additional information on the above subject, which the consideration of my present evidence has rendered advisable.

My object is to determine the greater or lesser importance of the constitutional factor in disease, and while still relying mainly on data derived from information respecting twins and doubles, I wish to draw upon all subsidiary sources, so as to obtain as complete an outline of the subject as is possible.

I have now evidence, though I should be glad of more, on the following points:—

(*a*) Similar particular diseases and definite constitutional conditions in true twins like and unlike in respect to: melancholia, broncho-pneumonia, chorea, splenic anæmia, diabetes, hernia, influenza, quinsy and tonsillitis, conjunctivitis, bronchitis, convulsions, thrush, typhoid fever, scarlet fever, measles, cyclical vomiting, pulmonary tuberculosis, peritonitis, caries of similar teeth.

From the literature of the subject instances of suicidal insanity, exalted delusions, melancholia, mania, idiocy, imbecility, congenital deformities, conjunctivitis, and most of the commoner specific fevers.

(*b*) Cumulative evidence of several similar diseases contracted nearly or quite simultaneously, sometimes in twins not living together.

Confirmatory evidence from literature of the subject:

(*c*) Cumulative evidence in triplets.

(*d*) Reference to insanity in triplets.

(*e*) Other characteristics shared in common in twins and triplets.

Confirmatory evidence from literature of the subject:

(*f*) Twins not of the same sex. Much less similarity, but not unlikeness of constitution.

(*g*) "Doubles," two cases of particular diseases—diabetes, tetanus.

(*h*) "Doubles," one case of cumulative evidence.

(*i*) Dissimilar diseases in twins, one doubtful case.

For help in collecting these instances together, I wish specially to thank Drs. D. Biddle, C. and H. Campbell, S. Davies, R. Glass, Goring, R. Hutchinson, A. D. Lewis, H. Maudsly, George Murray, H. Rayner, W. J. Rutherford, W. C. Sullivan, F. W. Ewart, Urquhart, and others of Great Britain; Drs. M. J. Conlin, C. Hedger, H. Lyons, Hunt, J. Ratcliffe, Milton Sturges, J. M. Trigg, and H. Yoder of America, and Dr. H. Rugg of Australia for useful suggestions and valuable particulars kindly given, and all others who replied to my inquiries. I am also much indebted to the various medical journals which kindly afforded me space for my inquiries.

Further data required:—

1.—SIMILAR DISEASES IN

(*a*) *Twins and triplets of the same sex.*

Like twins and triplets: Instances of one disease; or, if possible, of several diseases.

Unlike twins and triplets: Instances of one disease; or, if possible, of several diseases.

(*b*) *Twins and triplets not of the same sex.*

Like twins and triplets: Instances of one disease; or, if possible, of several diseases.

Unlike twins and triplets: Instances of one disease; or, if possible, of several diseases.

(*c*) "*Doubles*" *same sex, preferably adults.*

Instances of one disease; or, if possible, of several diseases.

(*d*) *Husband and wife.*

Like, the likeness consisting in similar eye colour, similar complexion, similar height characteristics, allowance being made for the fact that women are about four to five inches shorter than men.

Unlike in above particulars.

(*e*) *Parents and children.* Like. Unlike.

(*f*) *Brothers and sisters.* Like. Unlike.

2.—DISSIMILAR DISEASES IN

(*a*), (*b*), (*c*), (*d*), (*e*), (*f*), as quoted above.

I should be glad, as the evidence is often difficult to interpret rightly to have as many particulars in each case as possible.

I cannot find satisfactory evidence for the statement that true uniovular twins are *always* of the same sex, if any of your readers could supply me with references to detailed series of observations on this point I should be still further obliged.

I am, Sir, yours truly,
J. LIONEL TAYLOR.

8 Adys Lawn,
Willesden Green, London, N.W.

MEDICAL INSPECTION OF CHILDREN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The majority "of us" are grateful for the attitude you are taking up over the appointment of county M.O.H.'s as medical inspectors of schools.

The chief point is—"Are practitioners and specialists in medicine, surgery and diseases of children to be permanently barred from the posts because, forsooth, they have not the Diploma in Public Health?" If so, the posts are available only to a very small fragment of the profession, and that small fragment not specially trained and experienced in the diagnosis and treatment of children's diseases—congenital or acquired. A point apparently overlooked by the "powers that be" is that in the curriculum for D.P.H. a course in children's diseases is conspicuous by its absence.

Had it been a question of ventilation and inspection of school buildings alone, then there could be no doubt as to the value of such a diploma. But the county M.O.H.'s do this already, and then the children are to be inspected. So much have the majority of these diplomates laid aside the duties of everyday medicine and surgery (in many cases never writing even a simple tonic prescription or advising as to a suitable regimen) that instead of them being eligible to the exclusion of general medical practitioners, the reverse might with more justice be laid down, namely, that men in active practice should be eligible, and D.P.H.s not in general practice almost barred.

The Government are being led by the M.O.H.'s—they having no others to advise them, and unless we act the appointments will fall into the hands of a limited number of medical men.

Trusting you will give this important question your kindly consideration,

I am, Sir, yours truly,
MEDICUS.

June 11th, 1908.

SIR VICTOR HORSLEY ON MR. TROUTBECK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Sir Victor Horsley's latest public utterance should go some way towards promotion of amendment of the peculiar methods of "crowner's quest" which have been for so long displayed in the inquiries conducted by Mr. Troutbeck. Of these methods Sir Victor Horsley's criticism constitutes an indictment the force of which is not diminished by the moderation of the language in which it is expressed. Sir Victor furnishes exemplifications of the results of Mr. Troutbeck's system such as have been so often illustrated and commented upon in your columns, and points out that the system has for years led to a widespread miscarriage of justice. Mr. Troutbeck has systematically abstained from calling before the jury the medical practitioner actually in charge of the case, and has employed an outside pathologist who has never seen the patient during life, and has mostly had no communication whatever with the practitioner in charge. Sir Victor's specific complaint of the moment refers to a case in which Mr. Troutbeck held an inquiry into the death of a hospital patient who was dying, and did die, from the effects of a cerebellar tumour. The case was a perfectly simple one, and if it really called for an inquest, such an inquiry must be deemed necessary in every case of death during medical treatment of any kind. This is the absurdity to which Mr. Troutbeck's method, pursued to its logical end, must lead. Some means of putting Mr. Troutbeck under sufficient official restraint will be no doubt devised before much further approach is made towards so grotesque a consummation. That he has been allowed to go on so long without effective interference manifests once more the political impotence of the profession, its incapacity to make its voice heard in denunciation of a grievance even when of much greater importance to the community than to the medical practitioners.

I am, Sir, yours truly,
S. W.

IS THE TREDELENBURG POSITION ORIGINAL?

To the Editor of The Medical Press and Circular.

Sir,—While looking over some volumes of the *Provincial Medical Journal*, I observed the following, by Dr. H. Del Agémère, copied from *Le Progrès Médical*, Paris, June 1st, 1891:—"One of the difficulties in operations on the uterus and appendages is the presence of the intestines and their tendency to obscure the view of the operator. The author has got over this difficulty by placing the patient over an inclined plane; when so placed the knees and half the trunk are raised to a considerable height above the head. The bowels thus fall away by their own weight from the pelvic basin. The patient is rendered insensible before being placed in the inclined position." If this is not the Tredelenburg position I should like to know how it differs?

I am, Sir, yours truly,
Alexander Duke.
London, W.

THE OLDEST HOSPITAL FOR SICK CHILDREN IN THE UNITED KINGDOM.

To the Editor of The Medical Press and Circular.

Sir,—To prevent misconception such as has occasionally arisen in the past and which might arise again in the future from the recent letter to the papers from the secretary of the Royal Waterloo Hospital, may I ask you to state that the first hospital for Sick Children to be established in this country was the Hospital for Sick Children, Great Ormond Street.

The treatment which the Royal Waterloo Hospital afforded before 1852, the year of the foundation of the Great Ormond Street Hospital, and for many years after that date, was dispensary treatment only.

How great was the need of a children's hospital at that time may be gathered from the fact that in January, 1842, out of 2,363 persons in all the London hospitals only 26 were children under the age of 10, while of 50,000 persons dying annually in the Metropolis 21,000 were children under that age.

I am, Sir, yours truly,
Stewart Johnson, Secretary.
Hospital for Sick Children,
Great Ormond Street, London, June 9th, 1908.

A memoir of the late Edmund Symes-Thompson, M.D., F.R.C.P., physician 40 years to the Brompton Hospital for Consumption, by his wife, with a preface by the Bishop of Wakefield, has just been published.

OBITUARY.

JOHN DUNLOP, M.D.Aberd., L.R.C.P. and S.Ed.

We regret to have to record the death of Dr. John Dunlop, of Bradford, which took place on June 5th after a somewhat long illness. Dr. Dunlop was of Scottish birth, but he had resided in Bradford so long that he had almost come to be looked upon as a native of the city. In everything in which he bore a part he was enthusiastic, and the cause of enthusiasm in others, and his death will consequently create a gap in the friendships of many men in Bradford. Born on August 28th, 1840, at Dolphinton, Lanarkshire, Dr. Dunlop as a youth received his medical education at the school attached to the Royal College of Surgeons, Edinburgh, and took the diplomas of L.R.C.P. and L.R.C.S., Edinburgh, in 1863. He then proceeded to Marischal College, Aberdeen, where he studied under his friend and teacher, the late Sir John Struthers. In 1864 he became M.D. of that University. For many years Dr. Dunlop had held the appointment of medical officer to the Bradford Post Office, and he was one of the oldest members of the Bradford Medico-Chirurgical Society, being for many years treasurer of that body. He was also a very active member of the Bradford Medico-Ethical Society, now merged in the British Medical Association. For the long period of thirty years he was a member of the committee of the Bradford Nurses' Institution, and at the time of his death he occupied the position of Chairman.

EDWIN RICKARDS, M.A.Oxon., M.B., F.R.C.P., F.R.C.S.

We regret to record that the death took place at Edgbaston, Birmingham, on June 11th, of Dr. Edwin Rickards, one of the leading physicians in the Midlands. He was President of the British Medical Association in 1880, and in 1902-4 was President of the Birmingham Medical Institute. In his early career Dr. Rickards was House Surgeon at University College Hospital, London. Subsequently he was connected in an honorary capacity with the General Hospital, Birmingham, and other medical charities of the city. He was a Justice of the Peace for the county of Warwick, and one of the best-known medical leaders in Birmingham.

JOHN O'NEILL, L.R.C.P. and S.Edin., L.F.P.S. Glasg.

Dr. John O'Neill has died somewhat suddenly at his residence, Beckett Cottage, Burmantofts. On May 30th broncho-pneumonia set in, and death took place on June 1st. Dr. O'Neill, who was 41 years of age, was a native of Glanworth, County Cork. After studying at Queen's College, Cork, he went to the Universities of Glasgow and Edinburgh, and gained the degrees of L.R.C.P., L.R.C.S., and L.F.P.S. in 1889. For a short period he acted as an assistant at Halifax, and then began on his own account in the East-end district of Leeds. He built up a large practice among the poorer classes, by whom he was greatly respected. When the recent re-arrangement of the districts of the Leeds Union was made, Mr. O'Neill was appointed Medical Officer of the No. 11 district, which comprises a large portion of the East-end of the city.

SIR JAMES ARTHUR HANBURY, K.C.B., M.B., Hon. F.R.C.S.Eng. and Irel.

We regret to report the death of Sir James Arthur Hanbury, K.C.B., Hon. F.R.C.S. Sir James, who had reached his 76th year, was a retired Surgeon Major-General. He entered the Army Medical Department fifty-five years ago. He became Surgeon 1863, Surgeon-Major 1873, Brigadier-Surgeon 1879, Deputy Surgeon-General 1881, and Surgeon-General 1887. His first services were in China, India, and America; but his greatest distinction was gained in connection with the Afghan campaigns of 1878-80. In the Khyber in 1879, when cholera was raging in the pass, Dr. Hanbury was the principal medical officer, and his services were of such sort that he was several times mentioned in despatches, and especially thanked by the Governor-General in Council and by the Indian Commander-in-Chief. He served on the march from Cabul to Kandahar, and was present at the battle of Kandahar, September 1st, 1880. He also served as principal medical officer in the Egyptian Campaign of 1882, with the rank of Surgeon-General, and took part in the battle of Tel-el-Kebir. Sir James received the distinction of K.C.B. after this campaign, and the Distinguished Service Award in 1905.

REVIEWS OF BOOKS.

DISEASES OF THE NERVOUS SYSTEM. (*a*)

This work on "Diseases of the Nervous System" is one of unusual interest to British readers, for it presents a series of articles—monographs, we might almost say—by German neurologists of eminence. As confirmatory of, and supplemental to, the works on the subject in this country, it will be found to have a high practical value, and we warmly commend its perusal to all interested in the topics of which it deals. The language and expressions used are a little different to what we are accustomed, for the translation of German articles by an American produces as a result a compound of sententiousness and modernism with a touch of pedantry, and we do not find the mixture a very convenient medium for conveying the thoughts of the authors. In a word, the style is heavy, and not very lucid, and the reader has to follow every word closely to be sure he catches the exact drift of the author's mind. Even then he is not always successful. But, as was said above, this work is evidently not intended for the tyro, and the instructed will find so much good matter in it that he will not be deterred by the style from delving deeply. It is very good to look at our daily problem again from a fresh point of view, and no British neurologist will read this work without having his mind stimulated by fresh thought, fresh criticisms, and fresh facts. For ourselves, we are particularly struck by Dr. W. Erb's articles on locomotor ataxy and Parkinson's disease; by Dr. P. Schuster's very clever dissertation on traumatic neurosis; and a refreshing account of sexual neurasthenia by Dr. A. Eulenburg. A very high standard, however, is maintained throughout, and it is somewhat invidious to particularise, and detailed criticism of so important a work by so many contributors could only be attempted in much more space than is here at our disposal. The book represents a high achievement, for which we are grateful to authors, editors, and publisher alike, and we have no hesitation in saying that no English-speaking neurologist can afford to be without it.

THE PHILOSOPHY OF DISEASE. (*b*)

In all the ages there has been, on the part of those whose minds turned to speculative pursuits, a desire to arrive at first principles. Among other principles, that unifying the phenomena of disease was and is, naturally, an object of search. The present portentous volume sets out at great length one of the oldest theories of the philosophy of disease. The plan of the work is a peculiar one. The author might have taken as his motto the words of Montaigne, "I have culled a bouquet of flowers, and brought nothing of mine own but the string that binds them." Not only in arrangement, indeed, does the work seem to belong to the era of "Elegant Extracts," but also in its knowledge, for few authorities are quoted later than those of the early Victorian age. Nevertheless, Mr. Russell has a wide taste. He quotes largely from the father of medicine, from Boerhaave, from Sydenham, and from the great men of the past, but he does not exclude an extract from the *Family Herald*, "a leading article, probably written by a University man," nor various cuttings from the *Athenæum* of the first half of the last century.

Mr. Russell's extracts are sorted out under various headings, "Indigestion," "Consumption, etc.," "Headaches," "Epidemics," and some score or more of others, each, however, being introduced by a few lines of his own. One might think that it would be a matter of difficulty to discover in this large mass the kernel of medical philosophy. Fortunately, Mr. Russell, however he may like to support his position by the opinions of others, is himself the tersest of philosophical writers. He sums up his principle in one line in a quarter-page introduction—"He now proposes that 'putrefaction' and 'bacteria' are synonymous." As stated at more length in the opening paragraph of many of the chapters, his doctrine is:—"All disease is the same in all parts of the body; its cause, morbid humour; its source, indigestion and constipation, or the putrefaction arising therefrom; . . . its remedy, purgatives" (p. 125). We cannot but reflect that in this quotation Mr. Russell accurately describes the ætiology and genesis of his own volume.

MANUAL OF PRESCRIBING. (*a*)

The art of prescription-writing is, we have good reason to believe, falling into disuse. It has, therefore, become necessary within recent years to call the attention of teachers in medical schools to the importance of giving instruction in this important subject to their students. Accordingly, Dr. Marshall's little manual appears very opportunely. It deals with the various orthodox modes of administering medicines, with solubilities, incompatibilities, and dispensing. The section on incompatibility is one which will be studied most closely by readers of this volume, for this is a subject concerning which a great many students, and practitioners, for that matter, have very confused ideas. Another very useful chapter is the one on the forms in which medicines may be administered. This chapter contains a number of excellent illustrative prescriptions, characterised for the most part by their simplicity of construction, and always by their accuracy. This chapter occupies one-third of the entire volume.

The section which deals with dispensing will be found valuable by students and also by practitioners who dispense (*i.e.*, in the strict sense) their own medicines. Here we find a very clear account given as to the making of suppositories, and even of capsules, which we fancy few medical men take the trouble to make for themselves. The author maintains that the only royal road to efficient prescribing is through the portals of dispensing. With this we heartily agree. There is no doubt that many mistakes in prescription-writing are made simply from a lack of the practical knowledge of dispensing.

An appendix is added which contains an account of the Latin used in prescribing, and a very full English-Latin vocabulary. This we consider is by no means the least useful part of this admirable manual. The teaching given is throughout sound and practical, and we can unhesitatingly recommend this volume for use either as a students' text-book or as a work of reference for the practitioner. The writer's wide experience as a teacher has enabled him to produce a work which is at the same time scientifically accurate as well as easy of comprehension. It will certainly take its place as a standard text-book on the subject with which it deals.

THE POLICE SURGEON'S EMERGENCY GUIDE. (*b*)

A very useful little book of tips for police surgeons, tips also which may be of great service to any medical man if called upon by the police in his professional

---

(*a*) "Diseases of the Nervous System." By Archibald Church M.D., Professor of Nervous and Mental Diseases and Medical Jurisprudence, North-Western University Medical Department, Chicago. An Authorised Translation from "Die Deutsche Klinik," under the general Editorial Supervision of Julius Salinger, M.D. One hundred and ninety-five illustrations in the text and five coloured plates. London: Sidney Appleton. 1908. Price 25s. net.

(*b*) "Medical Philosophy; Man's Peculiarities, Weaknesses, Diseases, Degeneration, and Remedies." By W. Russell. Pp. xiv, and 504. London: Henry Kimpton. 1907. Price 21s. net.

(*a*) "A Manual of Prescribing for Students and Practitioners." By C. R. Marshall, M.D., Professor of Materia Medica and Therapeutics in the University of St. Andrews. London: J. and A. Churchill. 1908. Price 5s. net.

(*b*) "Police Surgeon's Emergency Guide." By C. Graham Grant, L.R.C.P. and S.Edin. Pp. 77. London: H. K. Lewis.

capacity. We quite agree with the modest words of the author in his preface, especially when he says:—“. . . This little book may rest unseen in the pocket, and perhaps justify its existence by saving its owner from making the little slip that leads to trouble,” and, we might add, “from cutting the sorry figure seen in the person of some medical men when giving professional evidence in the coroner's, police, or law courts.” This handy little volume should therefore form part of the *armamentarium* of all police surgeons, and also of any medical man who may be called upon to give skilled evidence in the courts. It is a pity the author does not facilitate the finding of the various tips by an index.

THE OXFORD PHYSIOLOGISTS. (a)

JUST two hundred and forty years ago the Oxford University Press published the celebrated “Tractatus Quinque” of John Mayow, and we gladly welcome Professor Gotch's lecture, issued by the same press, and drawing attention to the truly wonderful work which Mayow accomplished. The middle of the seventeenth century appears to have been the brightest period in the scientific life of Oxford University, and John Mayow stands out as pre-eminently among the great men of the time. Professor Gotch has endeavoured to explain why, not only the men of his own time, but scientists for more than a hundred years afterwards, failed to realise the value of the work contained in this small volume of five essays, but we cannot say that the explanation is very satisfactory. Richard Hook, no doubt, published the very imperfect abstract of Mayow's work which appeared in the “Transactions of the Royal Society,” but Mayow's work was published by the Oxford University Press, and was translated into Dutch and issued at Amsterdam in 1688, and so, at all events, was available in its complete form for the use of scientific inquirers. Mayow died five years after the publication of his work, and it seems to us that this work was overlooked, as the work of many another has been since, simply because the author was unable to insist on its importance by constant reiteration. Whatever may be the explanation, we are glad to think that now, at all events, Oxford recognises the worth of her great son, and our thanks are due to Professor Gotch for the very interesting account which he has given of him. The original editions of Mayow's works are difficult to obtain, but last year the Alembic Club, of Edinburgh, published an English translation of the “Tractatus Quinque,” and we could have wished that Professor Gotch had urged his readers to study for themselves this most interesting volume.

A CHRONOLOGY OF MEDICAL HISTORY. (b)

VERY little attention has ever been paid in these countries to the study of medical history, and there is, perhaps, no subject connected with his profession of which the general practitioner is more ignorant. The works of Freind, Leclerc, Wise, Berdoe, Withington and Hamilton seem to be almost unknown to many medical men, and certainly are not read by most. It has always seemed to us a pity that every doctor has not some general knowledge of the history of his profession; but perhaps the establishment of the Fitzpatrick Lectureship in London may do something to remedy the defect. The little book before us gives a brief epitome, with dates, of some of the chief events in medical history, and of the men who took part in them. It does for English students what Spemann's “Historischer Medicinal-Kalendar” does for Germans, though perhaps not quite so well. There are some curious omissions in the book, such, for instance, as 1846. One would have expected that the date of the introduction of artificial anæsthesia for surgical purposes was of sufficient interest to be mentioned. Graves is mentioned, but there is no record of his greater colleague, Stokes. More care might have been expended in verifying the dates, for we find Clopton Havers described as living from 1550 to 1702. This may, of course, be a mere typographical error, but it is difficult to account in this way for the dates associated with the name of John Howard. The date of his birth cannot be absolutely fixed, but it is generally agreed that it cannot have been later than the end of 1727, while our author puts it at 1766. We lay stress on these, which may seem minor points, because we consider that in a book of the kind accuracy is essential.

PROCEEDINGS OF THE ROYAL SOCIETY OF MEDICINE. (a)

WHETHER the union of the Medical Societies of London will prove to be all that its promoters promised it would be, is a matter which only the future can decide. There can, however, we think, be little doubt that the publication of these proceedings will be of the very greatest value to all students of medicine. One has here gathered together the reports of practically all the work of the London School of Medicine, and these reports are presented monthly while the matter with which they deal is still fresh. It is impossible for us in the space at our disposal to even indicate the great mass of material in all branches of medical knowledge contained in these reports, but it is sufficient to say that here we have a full account of the proceedings of all the chief medical societies of London. The form in which these reports are presented, and the excellence of the illustrations, reflects the greatest credit on the publishers, Messrs. Longmans, Green and Co.

HUMAN ANATOMY. (b)

WE have again the pleasure of welcoming a volume of Professor McMurrick's sumptuous anatomy. Volume III. deals with the Vascular System, the Lymphatic System, the Nervous System, and the Sense Organs, and it exhibits the same qualities as its predecessors. That is to say, it presents to the profession a series of diagrams, mostly in colours, which stand unexcelled for beauty and faithfulness of all the important and many of the less important parts of the body, together with accurate, lucid, and unencumbered accounts of regional anatomy. We doubt if pictorial art has ever achieved anything higher in the domain, in human anatomy, than figure 551, showing a dissection of the neck and axilla. It is more than lifelike because it shows the contrasts between the parts even more vividly than the actual subject, alive or dead, does. We need not say more than that to the student this book should prove an “Anatomy without Tears,” and to the practitioner a ready-made dissecting-room ever at his elbow.

AN INTRODUCTION TO DERMATOLOGY. (c)

THE fourth edition of this, the best-known of the smaller works on dermatology, marks an important advance on previous editions. While the size has been greatly increased, the author has nevertheless kept to the condensed yet easy style of treatment that gives a peculiar attraction to his writings. We notice that alopecia areata is treated as a symptomatic malady of multiple origin, and the theory of infection is accepted, as well as a nervous origin, while Mr. Hutchinson's theory that it is a sequel of ringworm is discussed, as well as Sabouraud's specific micro-organism. We note, however, that no mention is made of the syphilitic form described by some observers, nor of the variety associated with myxœdema and other constitutional affections. Lactic acid is advised as an excellent remedy, a point upon which those who have tried that drug will agree. Dr. Walker is emphatic upon the desirability of excluding a child from school when affected with alopecia patches. There is much to support that view both on grounds of prudence and for other obvious reasons. One of the great features of the present edition is to be found in a number of excellent illustrations in three-colour reproduction process. They are of first-rate quality, and greatly add to the value of the book. There is no particular need to criticise at length the contents of a work that has attained the dignity of a fourth edition. Suffice it to say that Dr. Norman Walker has here ably maintained the reputation of the Scotch school of dermatology. For any medical man who wants a crisp, readable, and eminently clear guide to the study of diseases of the skin, we can imagine no more useful volume to place on his bookshelf.

(b) “A Chronology of Medical History.” By James Young, M.D. 8vo, pp. 91. Bristol: Edward Everard.

(a) “Proceedings of the Royal Society of Medicine.” Edited by John Nachbar, M.D. Vol. I, Nos. 2, 3 and 4, December 1907 to February 1908. London: Longmans, Green and Co.

(b) “Atlas and Text-Book of Human Anatomy.” By Dr. Johannes Sobotta, Professor of Anatomy in the University of Würzburg. Edited, with additions, by J. Playfair McMurrick, A.M., Ph.D., Professor of Anatomy in the University of Michigan. Vol. III, Vascular, Lymphatic, and Nervous System, and Sense Organs. Two hundred and ninety-seven illustrations, mostly in colours. Philadelphia and London: W. B. Saunders Co. 1907. Price 25s.

(c) “An Introduction to Dermatology.” By Norman Walker, M.D., F.R.C.P., Physician for Diseases of the Skin, Royal Infirmary, Edinburgh. Fourth edition. Edinburgh and London: William Green and Sons. 1908. Price 9s. 6d.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

Sidney Appleton (London).

Diseases of the Breast, with special reference to Cancer. By W. L. Rodman, M.D., LL.D. Illustrated. Pp. 385. Price 16s. net.

Baillière, Tindall and Cox (London).

Physical Signs of Diseases of the Thorax and Abdomen. By James E. H. Sawyer, M.A., M.D.Oxon., M.R.C.P.Lond. Illustrated. Pp. 188. Price 5s. net.

The Treatment of Gonorrhœa in the Male. By Charles Leedham-Green, M.B., F.R.C.S. Second Edition. Illustrated. Pp. 160. Price 5s. net.

A Manual of Diseases of the Eye. By Charles H. May, M.D., New York, and Claud Worth, F.R.C.S.Eng. Second Edition. Illustrated. Pp. 400. Price 10s. 6d. net.

Diphtheria in Practice. By W. F. Litchfield, M.B.Syd. Illustrated. Pp. 96. Price 3s. 6d. net.

Lectures on Babies: A Course of Lectures delivered at the Infants' Hospital, Westminster. By Ralph Vincent, M.D., B.S., M.R.C.P. Illustrated. Pp. 114. Price 2s. 6d. net.

J. B. Baillière et Fils (Paris).

La Diathese Urique. Par Henri Labbe, Chef de Laboratoire a la Faculte de Medecine de Paris. ("Les Actualites Medicales.") Price Fr. 1.50.

Cassell and Co., Ltd. (London).

Clinical Methods. A Guide to the Practical Study of Medicine. By Robert Hutchison, M.D., F.R.C.P., and Harry Rainy, M.D., F.R.C.P.Ed., F.R.S.E. Fourth Edition, revised. Pp. 632. Price 10s. 6d.

Hygiene and Public Health. By B. Arthur Whitelegge, C.B., M.D., etc., etc., and George Newman, M.D., D.P.H., F.R.S.E. Illustrated. New and Revised Edition. Pp. 650. Price 7s. 6d.

Churchill, J. and A. (London).

A Short Practice of Midwifery. By Henry Jellett, B.A., M.D. Dublin Univ., F.R.C.P.I., with a preface by Sir W. J. Smyly, M.D., F.R.C.P.I. Fifth Edition, revised and illustrated. Pp. 654. Price 10s. 6d. net.

A Manual of the Practice of Medicine. By Frederick Taylor, M.D., F.R.C.P. Eighth Edition. Pp. 1,111. Price 16s. net.

Uric Acid as a Factor in the Causation of Disease. By Alexander Haig, M.A., M.D.Oxon., F.R.C.P. Seventh Edition. Pp. 940. Price 14s. net.

Eliot Boothroyd (London).

Low's Handbook of the Charities of London, 1908. Pp. 278. Price 1s.

Henry Frowde and Hodder and Stoughton (London).

Oxford Medical Publications. Glandular Enlargement and Other Diseases of the Lymphatic System. By Arthur Edmunds, M.B., M.S., B.Sc.Lond., F.R.C.S.Eng. Pp. 230. Price 7s. 6d. net.

Diseases of the Spinal Cord. By R. T. Williamson, M.D. Lond., F.R.C.P. Illustrated. Pp. 342. Price 15s. net.

The Law in General Practice: Some Chapters in Every-day Forensic Medicine. By Stanley B. Atkinson, M.A., M.B., B.Sc., of Inner Temple, Barrister-at-Law. Pp. 239. Price 7s. 6d. net.

The Operations of General Practice. By Edred M. Corner, M.A., M.C., M.B., etc., etc., and H. Irving Pinches, M.A., M.B., B.C., etc., etc. Second Edition. Revised and Enlarged. Pp. 338. Price 15s. net.

A System of Syphilis in Six Volumes. Edited by D'Arcy Power, M.B.Oxon., F.R.C.S., and J. Keogh Murphy, M.D., M.C., F.R.C.S., with an Introduction by Jonathan Hutchinson, F.R.C. Vol. I. Pp. 380. Price £2 2s. net per vol.

Henry J. Glaisher (London).

Hay-Fever, Hay-Asthma, Its Causes, Diagnosis, and Treatment. By Wm. Lloyd, F.R.C.S. Second Edition. Pp. 101. Price 4s. 6d. net.

Wm. Green and Sons (Edinburgh).

An Introduction to Dermatology. By Norman Walker, M.D., F.R.C.P. Illustrated. Fourth Edition. Pp. 332. Price 9s. 6d. net.

Charles Griffin and Co., Ltd. (London).

Forensic Medicine and Toxicology. By J. Dixon Mann, M.D., F.R.C.P. Fourth Edition, revised and enlarged. Pp. 709. Price 21s.

Greening and Co., Ltd. (London).

Education, Personality, and Crime. A Practical Treatise built up on Scientific Details, dealing with Difficult Social Problems. By Albert Wilson, M.D.Edin. Illustrated. Pp. 296. Price 7s. 6d. net.

G. Gillies and Co. (Glasgow).

The Practical Medicine Series. (10 Vols.) Under the General Editorial Charge of Gustavus P. Head, M.D. Vol. I. General Medicine. Edited by Frank Billings, M.S., M.D., and J. H. Salisbury, A.M., M.D. Pp. 408. Price 6s.

The Practical Medicine Series. (10 Vols.) Vol. II. General Surgery. Edited by John B. Murphy, A.M., M.D., LL.D. Pp. 614. Price 8s.

The Practical Medicine Series. (10 Vols.) Vol. III. The Ear, Nose, and Throat. Edited by C. A. Wood, C.M., M.A., A. H. Andrews, M.D., and G. P. Head, M.D. Pp. 355. Price 6s.

H. K. Lewis (London).

Public Health Laboratory Work. By Henry R. Kenwood, M.B., D.P.H., F.C.S. Part dealing with Public Health Bacteriological Work is contributed by W. G. Savage, M.D., B.Sc., D.P.H. Fourth Edition. Illustrated. Pp. 468. Price 10s. net.

Materia Medica and Pharmacy for Medical Students. By Reginald R. Bennett, B.Sc.Lond., A.I.C. Pp. 221. Price 4s. 6d. net.

Rough Notes on Remedies. By Wm. Murray, M.D., F.R.C.P. Lond. Sixth Edition. Pp. 192. Price 4s. net.

Experimental Researches on Specific Therapeutics. By Prof. Paul Ehrlich, M.D., D.Sc.Oxon. (The Harben Lectures for 1907.) Pp. 95. Price 2s. 6d. net.

J. B. Lippincott and Co. (London).

The Diseases of Children. A Work for the Practising Physician. Edited by Dr. M. Pfaundler and Dr. A. Schlossmann. English Translation edited by Henry L. Shaw, M.D., and Linnæus La Fetra, M.D. Four Vols. Illustrated. Price £4 4s. net.

International Clinics. Edited by W. T. Longcope, M.D., Philadelphia, U.S.A., with Collaboration. Vol. I. Eighteenth Series, 1908. Price 35s. net for 4 Quarterly Volumes.

Longmans, Green and Co. (London).

Proceedings of the Royal Society of Medicine. Vol. I., No. 7. May, 1908. Pp. 88. Price 7s. 6d. net.

Rebman, Ltd. (London).

Vitality, Fasting, and Nutrition. By H. Carrington, with an introduction by A. Rabagliati, M.A., M.D., F.R.C.S. Pp. 648. Price 21s. net.

Electric Ions and their Use in Medicine. By Professor Stephane Leduc. Translated by R. W. Mackenna, M.A., M.B., Ch.B.Edin. With an Appendix by the Translator. Only Authorised Translation from the French Edition. Pp. 70. Price 2s. 6d. net.

The Theory of Ions. A Consideration of its Place in Biology and Therapeutics. By William Tibbles, M.D.Chicago, LL.D., L.R.C.P.E., M.R.C.S., L.S.A., etc. Pp. 131. Price 2s. 6d. net.

The Scientific Press, Ltd. (London).

The Heart and Sudden Death. By Theodore Fisher, M.D., F.R.C.P. Illustrated. Pp. 53. Price 2s. net.

"The Pilot" Press (London).

Cancer: Operation not the Cure but a Cause. By John Shaw, M.D.Lond., formerly Vice-President, British Gynæcological Society, and (for upwards of 20 years) Physician for Diseases of Women, North-West London Hospital. Pp. 144. Price 1s. net.

J. Whitaker and Sons, Ltd. (London).

The Holiday Whitaker: A Guide to the Holiday and Health Resorts of the United Kingdom. Illustrated. Pp. 397. Price 1s. net.

John Wright and Co. (Bristol).

Golden Rules of Venereal Disease. By C. F. Marshall, M.D., F.R.C.S. Pp. 90. Price 1s.

Vermin Inquiry.

The Society for the Destruction of Vermin have appointed a special committee to inquire into the various existing laws and regulations concerning noxious insects and animals, to agitate for their more efficient and extended application, and to propose such amendments or promote such new laws as may be necessary to meet requirements in the light of modern knowledge, especially with regard to the all-important and recently ascertained *rôle* played by vermin in the dissemination of disease germs communicable to man and domesticated animals.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Symptomatology of Gastric Cancer.—Przewalski (*Zentralblatt f. Chiurgerie Leipsic*, April, 1908) calls attention to the contraction of the middle intercostal spaces on the right side of the thorax as an early sign of carcinoma of the stomach. It is probably a reflex contraction from the nerves of that part of the stomach wall most frequently affected with malignant disease. In the later stages all the intercostal spaces are contracted on both sides, as also in case of cancer of the œsophagus. He examines for this contraction with his finger tips between the axillary lines. D.

Chilling as a Cause of Sickness.—Siegel (*Deut. Med. Woch.*, March, 1908) has experimented on dogs, proving that the presence of bacteria *plus* the action of cold does not always cause disease. On the other hand, cold without bacteria is able to produce parenchymatous nephritis under certain conditions. The dogs in his experiments invariably developed a bilateral nephritis, even when only one foot had been immersed in ice water. In most of his experiments the hind legs of the animal were covered with ice water from the knee downwards at a temperature of 39° F. He explains this by the fact that chilling of the feet induces constriction of the renal vessels by reflex action, and if this reflex anæmia persists for a considerable time, it causes disturbances in the circulation and in the nutrition of the kidney cells, followed by degenerative changes, with inflammation as the final outcome. The chief result of these experiments is the proof that an acute kidney affection can be produced by chilling alone, without the presence of bacteria. D.

Müller's Test for the Functioning of the Pancreas.—(*Mün. Med. Woch.*, April, 1908).—This communication reports favourable experiences with Müller's test of pancreas functioning at Von Strumpell's clinic at Breslau. The simplicity and convenience of the test commend it, Schlecht says, while it is thoroughly reliable, and requires only a few drops of fæcal matter. Another advantage is that the material is sterilised by the high temperature. The test is based on the proteolytic action of the pancreatic ferment trypsin. The patient is given a test meal, and two hours later a calomel purge. A few drops of the thin stool then obtained are sown on a plate of Loeffler serum, which is kept for 24 hours at a temperature of 131° to 141° F. If there is any of the pancreatic ferment in the stool, the surface of the Loeffler serum shows pronounced depressions where the proteolytic ferment has been at work. In the absence of the pancreatic ferment the surface of the serum remains smooth, with no tendency to dimpling. D.

Diet in Nephritis.—Louria (*Long Island Med. Journ.*, March, 1908) discusses the physiologic chemistry of renal excretion in regard to diet. His experience enables him to support the French dechloridisation treatment. The salt-free diet certainly seems to cause a general improvement of the patient, the diminution of œdema, and a loss of weight, all of which seem to be parallel phenomena. Indeed, increase of weight in a nephritic may be interpreted as the first symptom of the beginning of an œdema not yet visible. He considers the idea that red meat is more harmful than white as exploded. As regards the quantity of meat, the nephritic should receive a daily ration of 100 grammes of albumin. Assuming that he takes 750 c.c. of milk, containing 26 grammes of albumin, two eggs, with 13 grammes of albumin, and that 20 grammes of proteid are in other food, as bread, vegetables, etc., there still remains 50 grammes of proteid that he can be allowed in the form of meat, which amounts to about half or three-quarters of a pound. D.

Alimentary Poisons and Atheroma.—Loeper (*Arch. des Maladies du Cœur des Vaisseaux et du Sang.*, Paris, 1908) gives illustrations of processes of calcification and atheroma found in the arteries of animals under the influence of certain alimentary poisons. If the diet could be strictly atoxic from beginning to end, then atheroma could be warded off, he says. Oxalic acid was particularly active in inducing atheroma in his rabbits, and he warns that rhubarb, spinach, and tomatoes contain an unusualy large proportion of oxalic acid, which is also present, he says, in large proportions in tea, coffee, kola and cocoa. The latter also contains, he states, from .65 to 2 per cent. of theobromin, and theobromin is another vascular poison, as he shows by the atheroma induced in rabbits by injection of theobromin acetate. Administration of lime salts had also a marked favouring action on the experimental atheroma. The lesions induced in his experiments were always calcification of the middle layer of the vessel wall. No tendency to sclerosis was ever noted. D.

Etiology of Plague in India..—Bannerman gives a critical analysis and summary of the recent researches of the Plague Commission into the etiology of plague in India (*Edin. Med. Journ.*, May, 1908, p. 417). The account itself must be read to gain any connected view of the work upon which the conclusions drawn are founded, but the general conclusions of the writer are of sufficient importance to quote without further comment. They are as follows:—(1) Pneumonia plague is highly contagious, but being rare (less than 3 per cent. of all cases), plays a very small part in the spread of the disease. (2) Bubonic plague in man is not infectious, and is entirely dependent on the disease in the rat. (3) The infection is conveyed from rat to rat, and from rat to man, solely by means of the rat flea. (4) Plague is usually conveyed from place to place by rat fleas, brought by people in their baggage or on their persons. M.

Enlargement of Supraclavicular Glands in Abdominal Carcinoma.—Schellschmidt observes that enlargement of the supraclavicular glands either on the right or left side is by no means a frequent occurrence in abdominal carcinoma (*Centralbl. für Inn. Med.*, No. 23, 1908, p. 585). When present, however, it is of considerable diagnostic value. The enlargement is nearly always caused by metastases, and is only occasionally of an inflammatory nature. The enlargement may also be found in scrofula, syphilis, leucæmia, and in malignant tumours of the mediastinum and lungs. In any doubtful case extirpation and microscopical examination of the suspected gland should be carried out. The metastatic growths are caused either by emboli or by continuous extension of the primary growth along the lymphatics, and glandular involvement in the neck is usually secondary to involvement of other organs, such as the liver. In consequence, gland metastases in the neck are an absolute contraindication to any operation, with the doubtful exception of cases in which the primary growth is in the cardiac end of the stomach. Once involved with cancer, the lymph glands very rapidly increase in size. M.

The Toe-Reflex.—Rossolimo describes a special toe-reflex which he states to be of considerable pathological importance (*Neurol. Centralbl.*, 1908. No. 10). The reflex is obtained as follows:—In individuals suffering from disease of the upper motor neurone, a short, quick stroking movement of the finger is made along the plantar aspect of the toes in the direction from behind forwards: the toes will then, after a variable interval, perform a characteristic movement of flexion or abduction, provided that the calf muscles and those of the foot are kept in a state of complete relaxation. Rossolimo states:—(1) That this toe-reflex is only obtained in cases where the pyramidal tracts are diseased, and is never found in simple neuroses. (2) That it can often be observed in cases where Babinski's sign is absent. (3) Its intensity varies much—from a scarcely perceptible movement, up to a smart contraction. (4) In contradistinction to other tendon reflexes, whose value depends upon an increase above the normal, this reflex, if present at all, is pathognomonic of disease, as it is never found in normal individuals. M.

Poisoning by Thiosinamin.—Thiosinamin and its ally, fibro-lysin, has been so largely used of late to cause absorption of morbid fibrous tissue, that it has become of importance to observe any untoward symptoms caused by its use. Grosse reports a case of poisoning following the injection of six doses of fibrolysin at intervals of five days (*Munch. Med. Woch.*, 1905. No. 17). The symptoms consisted of cardiac weakness, anuria, fever, vomiting, and severe debility. The sickness lasted altogether for four weeks, and was followed by recovery. M.

Treatment of Eczema of Infants by Thyroid.—Eason (*Scottish Med. and Surg. Journ.*, May, 1908) reports five cases of eczema in infants and young children which were treated entirely by small doses of thyroid extract with most excellent results. In each of the cases the children had been ill for some time previously, and had not improved in spite of careful and persistent local treatment. One of the children, æt. 9 months, had shown symptoms of eczema for two months, which persisted, in spite of the use of various ointments. A quarter of a grain of the thyroid was given daily, and in a week the eruption was very much better. A month later, when the rash was almost well, the child developed a severe attack of bronchitis; the drug was then stopped, but the child died of convulsions two days later. There seemed to be no reason to connect the thyroid with the fatal result, and at the time of death the child was practically cured of the eczema. Moussous, Parhon and Urechie have also recorded good results from this form of treatment. K.

X-Rays in the Treatment of Lupus.—Tomkinson (*Practitioner*, June, 1908) details the method which he has for the past two years adopted in the treatment of lupus vulgaris by X-rays. As a general rule this method of treatment is only adopted when the lesion is situated on some exposed part, and when, in consequence, the nature of the resulting scar is of considerable importance. If any crusts are present they are removed by an application of salicylic ointment, and then a tentative X-ray exposure of from three to five minutes' duration is made upon a small area of the lesion. If no ill result follows from this in the course of a few days, daily exposures are given of about five minutes' duration over a wider area until the whole lesion has been exposed some three or four times. It is then plastered with Unna's 50 per cent. salicylic acid and creosote plastermulle, which is renewed daily. If this causes much pain the parts may be swabbed with a 10 to 20 per cent. solution of cocaine previous to its application. In about ten days it is found that much of the tuberculous tissue has come away. The lesion is then swabbed with cocaine solution, dried, and afterwards painted with the following preparation:—Carbolic acid, 50 per cent.; lactic and salicylic acids, of each 15 per cent.; and absolute alcohol, 20 per cent. A few minutes afterwards the lesion is painted with a solution of 80 per cent. carbolic acid in absolute alcohol. In extensive cases it is well to cauterise only part of the lesion at a time, but as much as a whole cheek may safely be done at one time. After cauterisation the part is dressed for a day or so with carbolic oil, and then with a 20 per cent. aqueous solution of ichthyol until healing has taken place. As a rule the healing is rapid, and when it is complete the X-ray treatment is recommenced and continued for about three months. Only short exposures are given, rarely more than three or four minutes. Treatment is then discontinued for a considerable interval, during which time the patient returns periodically for inspection. Sometimes it is necessary to submit the patient to a second course, but this is only done after an interval of some months. Tomkinson states that this method has given excellent results, and the cicatrices resulting from this combined treatment of X-rays and cauterisation are, as a rule, smooth and flexible and show few telangiectases. K.

The Use and Abuse of Digitalis.—Janeway (*Amer. Journ. of the Med. Sciences*, June, 1908) states his belief that there are five chief causes of failure in the employment of digitalis. These are:—(1) The use of inefficient preparations; (2) use in unsuitable cases; (3) improper dosage; (4) improper methods of administration; and (5) neglect of other necessary therapeutic measures. It would appear that good digitalis is not at all plentiful, and that various specimens and preparations of the drug vary very much in their therapeutic activity. Janeway himself favours the infusion, provided it is freshly made from good leaves; but the tincture and the powdered leaves are also both reliable preparations. If the administration of digitalis by the mouth is followed by vomiting, administration by the rectum should be tried. An injection of half an ounce of the infusion three times a day will, as a rule, give as prompt results as administration by the mouth, while if a very rapid effect is needed hypodermic administration may be resorted to. K.

MEDICAL NEWS IN BRIEF

The Management of St. Bartholomew's Hospital.

Lord Ludlow (the treasurer) and the five almoners of St. Bartholomew's Hospital have resigned their posts because a unanimous recommendation made by them, which they considered all important for the future welfare and good management of the hospital, was not adopted by the court of governors. A court of governors was held on Thursday last, when the following resolution was unanimously adopted:—

"That in accepting the resignation of the Right Hon. Lord Ludlow of the office of treasurer, to which he was elected on January 26th, 1905, this court hereby records its deep sense of appreciation of the very valuable services he has rendered to the hospital. The important structural alterations and additions which have been carried out under his treasurership have added greatly to the efficiency of the hospital, and the advantages that have accrued to the institution as the result of the various reforms instituted by him in the management of the estates, and in the internal administration of its affairs, cannot be overestimated, and the court tenders to Lord Ludlow its grateful acknowledgments."

The almoners consented to postpone their resignation until July next, in order that the affairs of the hospital may be carried on whilst the new officers are appointed.

The Dublin Hospital for Diseases of the Skin.

A curious case was heard before Judge Barton during the past week in which the plaintiffs, consisting of one member of the staff of this hospital and one of its governors, sued the remaining member of the staff and the other governors with the object of obtaining an account of all sums of money paid from time to time by the Managing Committee of the hospital to the defendant member of the staff, Dr. C. M. O'Brien. These payments were stated to be made on foot of an alleged agreement between the committee and Dr. O'Brien, by which the committee agreed to purchase certain X-ray apparatus from Dr. O'Brien. These apparatus were to be paid for by instalments, and in the meantime Dr. O'Brien was to receive one-half of the profits of the working of the apparatus. The plaintiffs also asked for an account of all sums of money received by Dr. O'Brien from the South and the North Dublin Unions and other Poor-law Unions in Ireland from which patients were sent for treatment in the Hospital, which funds, it was charged, had never been brought to the credit of the funds of the hospital; also for sums of money received by Dr. O'Brien from patients not brought by him to the credit of the funds of the hospital. The defence was a traverse of the material allegations in the affidavits on behalf of the plaintiffs. The chief points of difference were as to whether the hospital was entitled, under the agreement, to receive half of the amount paid to Dr. O'Brien by the various Poor-law unions for treatment of patients at the private rooms of Dr. O'Brien in Mary Street.

Mr. Justice Barton directed an account to be taken from April 10th, 1902, of all moneys paid to Dr. O'Brien by the Poor-law Unions and other public bodies on foot of the agreement up to the present: also that Sir Robert Gardner should audit the accounts of the hospital, the account to be afterwards taken before the chief clerk, and that payments now being made to Dr. O'Brien should cease. His lordship further said that, if it had not been for Dr. O'Brien there would have been no such hospital in Dublin, and that he deserved much credit for the cures he had effected.

The Annual Meeting of the Royal Medical Benevolent Fund Society of Ireland.

The annual meeting of this Society was held during the past week, the President of the Royal College of Surgeons in the chair.

Sir John William Moore read the report of the Central Committee, which, having dealt with formal matters, noted some changes which had been rendered necessary in the list of the Society's officers, and paid tribute to the memory of members whose death had occurred since the previous annual meeting.

Dr. Joynt read the financial statement, from which it appeared that during the financial year 1907-8 eighty-four grants were awarded by the Central Committee, amounting to £1,127. Dividends on stock realised £785, an increase of £96 17s. 10d. on the preceding year. The Society received £71 9s. 6d. from the Dublin and South-Eastern Railway Company.

On the motion of Mr. Wm. Taylor, seconded by Mr. M'Namara, warmest thanks were passed to the Committee and officers of the parent Society, and the provincial branches for their hearty zeal.

On the motion of Dr. Bradley, seconded by Dr. W. H. Byrne, the Central Committee and other office bearers were re-appointed for the ensuing year.

Interesting Inquest.

On June 11th, at the City Coroner's Court, Dr. F. J. Waldo held an inquest with reference to the death of B. E. Clark, 17, a waiter, who died in St. Bartholomew's Hospital. Clark was crushed across the shoulders while trying to get out of a lift in October last. His spinal column was broken, and he was admitted to St. Bartholomew's Hospital, although he was paralysed from the middle of the shoulders downwards. During seven and a-half months that Clark was in the hospital he was visited by some of the most eminent surgeons, who took great interest in the gradual progress of the case. Everything possible was done to brighten Clark's life, and a special reading desk was fitted up above his bed to enable him to get as much comfort as he could in his helpless state. He died on Wednesday. Dr. Basil Lang, house surgeon at St. Bartholomew's Hospital, stated that Clark was completely paralysed when admitted, as his neck was broken. After a time an operation was performed for the purpose of seeing if the backbone was pressing on the spinal cord, and they then found that the cord was completely severed 2 in. below the brain. He had never had a similar case. The jury returned a verdict of "Accidental death," and added a recommendation that something should be done so that the lift could be worked outside as well as inside.

Charges Against a Medical Man.

The Waltham Abbey magistrates dealt on June 11th with two charges against Frederick Charles Ackland, 34, described as a physician and surgeon, of Brailsford Road, Brixton. In the first case the charge was brought by the N.S.P.C.C., and had reference to Mary McCarthy, 4 years of age. It was alleged that prisoner found the child and her sister Kate, who is two years older, playing in Lincoln's Inn Fields, and that, giving them chocolates and oranges, he persuaded them to go with him to Liverpool Street Railway Station, taking them thence to Epping Forest. The second charge was for contracting a bigamous marriage with Hetty Florence Gertrude Satchell. In her evidence Miss Satchell said she met the prisoner on September 14th, 1907, on board the *Pomeranian*, bound for Canada. She was travelling from London to Montreal, and he was engaged as doctor on the vessel. They became friendly, and on October 3rd they were married at St. George's Church, Montreal, she believing him to be a single man. Evidence was given of the prisoner's marriage on October 5th 1898, to Margaret Hankey at Dalton-in-Furness, and that she is still alive. Prisoner, who asked no questions, was committed for trial at the Essex Assizes.

Death by Compressed Air.

The death of an apprentice, Wilkinson, by name, at the Central Marine Engine Works, Hartlepool, was inquired into by a coroner's jury at Hartlepool on June 9th. Two fellow-apprentices, D. M. Johnson and W. H. Woodward, who have been remanded in connection with Wilkinson's death, were present. To his father, who saw him in hospital, Wilkinson had said: "What a foolhardy trick those boys have done to me. They have filled me with compressed air. I was standing at the bench, when the pipe was put between my legs. I felt myself swelling right out. What a funny sensation I had!" Woodward's story was that he picked up the pipe which serves compressed air to the pneumatic tools, intending to clean the bench with it. Johnson turned on the tap, and when the air came through the pipe the end flew up and caught Wilkinson between the legs. Another witness said that Wilkinson was blown up like a bladder. The stated maximum air pressure produced by the apparatus was 100 lb. per square inch. The jury exonerated the management of the works, and found insufficient evidence to show whether the youth had received the compressed air accidentally or otherwise.

Death under an Anæsthetic.

An inquest was held by Mr. W. Schroder, on June 9th, on Hortense Berthand, æt. 18, single, a French dressmaker. Mlle. Berthand suffered, it was stated, from an affection of the right ear, and after consulting a medical man, it was deemed advisable that she should undergo a surgical operation. For this purpose she entered the Central London Throat, Nose, and Ear Hospital, Gray's Inn Road. She was, M. Jan, her brother-in-law, said, informed before consenting to the operation that "she need not be afraid, as there would be no danger." The operation was being performed on Thursday, when death ensued whilst she was under the influence of an anæsthetic. The witness added that it was an outside practitioner who stated that there was no danger. Dr. D. Mackenzie, Assistant-Surgeon at the Hospital, stated that both Dr. Dundas Grant and he were of opinion that an operation in this case was urgent, and that if it were not performed the patient would certainly die from the disease from which she suffered—an abscess in the middle ear. Chloroform, and also a mixture of alcohol, chloroform, and ether, having been administered, the witness began to operate for the relief of the abscess, when the patient suddenly expired before the operation—which was not very serious in itself—could be completed. There were seven doctors present altogether, and everything possible was done with a view to resuscitation. The Coroner: It is said that she was told that she need not be afraid, as there would be no danger. Is that a statement likely to be made by a medical man? Dr. Mackenzie: I do not think so. If made, it would, perhaps, be qualified. The impression left on the girl's mind nobody can tell. Dr. B. Kingsford, the hospital anæsthetist, said he had administered the alcohol, chloroform, and ether mixture 10,000 times previously without fatal mishap. Dr. Wingrave, pathologist at the hospital, who had made an autopsy, attributed death to syncope whilst the patient was under the influence of the anæsthetics, which were not, he thought, administered in excess. The jury found a verdict of "Death by misadventure."

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

T. P.—We are glad to see that you value our opinion. You seem as well up in the modern development of surgery as we ourselves.

S. R.—No medical man should refuse to itemise his account if the patient wishes it. There may be far too much standing on dignity, and it is possible that a mistake may have been made. In following the fashion of sending in an account for a lump sum, it is by no means implied that a patient is not entitled to details if he wishes. Some business men do not understand the practice, and rather resent it. Medical men should be thankful they are not compelled to send in accounts as elaborate as that of a solicitor.

CITY OF LONDON CORPORATION MEDICAL EXAMINATION.

In accordance with the Standing Order of the Court, everyone now entering the employment of the Corporation in any capacity has to pass a medical examination. Last year 50 persons were so examined, and of these 7—or 14 per cent.—were reported by the Medical Officer as physically unfit for office. Nineteen officers were also medically examined with a view to their retirement, and of these 9—or 47.3 per cent.—were reported to be unfit for duty.—*City Press.*

G. E.—Thank you for calling our attention to the matter of the letter. We wish you all success.

C. E. R. (Miss).—We have written to you privately. The matter is not one in which we can give more than general advice, and, of course, we cannot recommend private practitioners. There is no need, so far as we can see, for you to come to London.

Scotsman.—Thank you for your interesting communication and enclosure. The matter is so important that we have ventured to make use of the former in the way you will see. We feel sure you will be agreeable.

F. W. L. (Liverpool).—We are much obliged for your letter and newspaper. As you see, we are dealing with this important matter more extensively this week.

Enquirer.—Vacant posts of the nature mentioned are not often announced in the English medical journals. Two such are advertised in our present week's issue at Sanatoria in New South Wales. For details we refer you to the announcement in another column.

Meetings of the Societies, Lectures, &c.

Wednesday, June 17th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. R. Johnson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. C. R B. Keetley: Affections of the Toes, Feet, and Ankles.

Thursday, June 18th.

Royal Society of Medicine (Neurological Section) (20, Hanover Square, W.).—4.30 p.m.: Clinical Meeting (at the Hospital for Epilepsy and Paralysis, 4, Maida Vale).

Royal Society of Medicine (Dermatological Section) (20, Hanover Square, W.).—5 p.m.: Clinical Cases: Dr. Graham Little: (1) Private Case for Diagnosis; (2) Private Case of Urticaria Pigmentosa in an Adult (with sections); (3) Two Cases of Pseudo-pelade (Brocq); (4) Sections of Skin from the Case for Diagnosis and the "Varus Nodulosus" shown at the last meeting.

Royal College of Physicians of London (Pall Mall East).—5 p.m.: Croonian Lecture:—Dr. A. E. Garrod: Inborn Errors of Metabolism.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. W. Langdon Brown: Diseases associated with Cyanosis.

Friday, June 19th.

Society of Tropical Medicine and Hygiene (20, Hanover Square, W.).—8.30 p.m.: Annual General Meeting. Dr. C. F. Harford: Tick Fever of Africa, with Special Reference to its Clinical Manifestations and its Relations to the Relapsing Fever of India and other parts of the World.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. A. Lawson: Clinique. (Eye.)

Vacancies.

Metropolitan Hospital.—Secretary. Salary, £350 per annum. Applications to the Chairman, Metropolitan Hospital, Kingsland Road, N.E., not later than June 20th. Canvassing will disqualify.

Royal Hampshire County Hospital, Winchester.—Secretary-Manager. Salary, £150 per annum. Applications to the Acting Secretary.

London County Asylum, Claybury, Woodford, Essex.—Assistant Medical Officer. Salary, £160 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6, Waterloo Place, London, S.W.

London County Asylum, Horton, Epsom, Surrey.—Assistant Medical Officer. Salary, £160 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6, Waterloo Place, London, S.W.

Manchester.—Chorlton-upon-Medlock Dispensary.—Resident Medical Officer. Salary, £120 per annum. Applications to the Secretary.

County Borough of Derby.—Medical Officer of Health. Salary, £600 per annum. Applications to G. Trevelyan Lee, Town Clerk, Town Clerk's Office, 15, Tenant Street, Derby.

St. George's Union, London.—Second Assistant Medical Officer. Salary, £120 per annum, with board, residence, and washing. Applications to the Medical Superintendent.

Enfield and Edmonton Joint Hospital Board.—Resident Assistant Medical Officer. Salary, £150 per annum, with rooms, rations, and washing. Applications to T. W. Scott, Clerk to the Board, Public Offices, Enfield.

St. Vincent's Hospital, Dublin.—A Physician and a Surgeon. Applications to Hon. Secretary. (See Advt.)

Incorporated Orthopædic Hospital of Ireland.—An Anæsthetist and an Assistant Anæsthetist. Applications to Captain J. W. Borthistle, Secretary. (See Advt.)

Appointments.

Dennis, A., L.D.S., L.R.C.P.Lond., M.R.C.S., House Surgeon at the Royal Dental Hospital of London.

Fletcher, E. E., L.D.S., to the Appliance Department of the Royal Dental Hospital of London.

Gemmell, Samson, M.D., C.M.Glasg., F.F.P.S.Glasg., Professor of the Practice of Medicine in the University of Glasgow.

Harwood, L. A., L.D.S., House Surgeon at the Royal Dental Hospital of London.

Mackenzie, Theodore Charles, M.B., F.R.C.P.Edin., Medical Superintendent of the Inverness District Asylum.

Murphy, Edward Ernest Albert, L.R.C.P. and S.Edin., L.F.P.S.Glasg., Assistant Medical Officer at the Devon County Asylum, Exeter.

Ovey, W. C., L.D.S., House Surgeon at the Royal Dental Hospital of London.

Skerrett, Frank B., M.B.Lond., D.P.H., School Medical Inspector for the County Borough of West Ham.

Smyth, F. R., L.D.S., House Surgeon at the Royal Dental Hospital of London.

Marriages.

Haig—Thorne.—On June 10th, at St. Mary's, Summerstown, Wandsworth, Francis Murray Haig, M.D., of Trevone, Woking, eldest son of the late Genl. Felix T. Haig, R.E., to Eliza Mabel, daughter of John Mills Thorne, of Burntwood Lodge, Wandsworth Common.

Heywood—Gibbs.—On June 11th, at the Parish Church, Moulsford, William Benjamin Heywood, M.D., M.A.Camb., second son of the late Benjamin A. Heywood, of Beckenham, to Josephine Frances Audrey, fourth daughter of the Rev. Joseph Gibbs, Vicar of Moulsford.

Rabagliati—Bright.—On June 10th, at Christ Church, Harrogate, Andrea H. Rabagliati, M.D., eldest son of Andrea C. F. Rabagliati, M.D., F.R.C.S.E., of Bradford, to Julia, fourth daughter of Frank J. Bright, Bentfield, Rochdale.

Rogerson—Attwell.—On June 9th, at St. Peter's Church, Morley, Frederick Rogerson, M.B., B.S., L.R.C.P.Lond., M.R.C.S.Eng., youngest son of William J. Rogerson, of London, to Jane, youngest daughter of the late George Attwell, of Portsmouth.

Smallhorn—Forster.—On June 10th, at Sevington Church, Ashford, Kent, Cyril Aubrey Smallhorn, M.A., M.B.Oxon., of Knutsford, only son of the late Dr. Thomas Smallhorn, of Eynsham, Oxford, to Isabella Maude, eldest daughter of the Rev. Bennet Forster, M.A., Rector of Sevington.

Deaths.

Maclean.—On June 12th at Charleville, Kew Gardens, Inspector-General Andrew Maclean, M.D., aged 96.

Rickards.—On June 11th, at Ellerslie, Augustus Road, Edgbaston Birmingham, Edwin Rickards, J.P., M.B.Oxon., F.R.C.P., consulting physician to the General Hospital, Birmingham, aged 66.

Mellin's Food

Rich in Flesh, Nerve, Brain, and Bone Formers.

THE ANALYSIS OF MELLIN'S FOOD SHOWS IT TO BE:—

1. Absolutely Free from Starch.
2. Free from Glucose or Cane Sugar.
3. Rich in Maltose, the analogue of lactose.
4. Alkaline in reaction.

Mellin's Food contains no dried milk and is anti-scorbutic. It modifies cow's milk, and makes it chemically and physiologically identical with breast milk.

Complete Tables of Analyses and Samples will be forwarded free to Members of the Medical Profession on application to MELLIN'S FOOD, LTD., Peckham, London.

SYR TOLU ET HEROIN
ELIXIR SALICYLIC
BROMO SODA
PARVULES

"I have used Effervescing **Bromo-Soda** very extensively, and can cheerfully recommend it to my professional brethren. The addition of the grain of Caffein Hydrobromate to the thirty grains of Sodium Bromide I think a most happy idea. I recommend your Bromo-Soda because I have used Sodium Bromide for years, instead of the Potassium Bromide. Sodium Bromide is not a foreign salt in the system, is much less depressant, can be used where the heart is extremely weak, and does not impair the integrity of the muscular tissue; does not cause bad breath, neither does it cause acne, nor impair pharyngeal sensibility. It is much more palatable, and has the happy faculty of agreeing with the stomach, where the corresponding Potassium Salt often gives us so much trouble. I find Effervescing Bromo-Soda very valuable in cases superinduced by overwork of a mental kind; in fact, at times, when overworked, I have refreshed myself with a little in water."—J. K. B——, M.D., LL.D.

"Bromo-Soda" (Registered) per Large Bot., 3/6.

PHYTIN

IS THE NATURAL SALT OF PHOSPHORUS, PRESENT IN SEEDS AND VEGETABLE TISSUES. NO OTHER DRUG CONTAINS SO LARGE A PERCENTAGE (22.8) of

ASSIMILABLE PHOSPHORUS.

Supplied in form of CAPSULES (each containing the Dose—4.2 grains), or in POWDER, or in LIQUID (for Club & Hospital Practice).

Society of Chemical Industry in Basle (Pharm. Dept.), 8 Harp Lane, London, E.C.

FORMAMINT

An Excellent Antiseptic and Prophylactic in Diseases of the Throat and Mouth

EFFICIENT SUBSTITUTE FOR GARGLES

COMPOSITION: Vide Article on "Oral Sepsis" in *The Lancet*, Oct. 20th, 1906.

"A chemical combination of Formic Aldehyde and Lactose put up in the form of a compressed tablet."

"A non-toxic and trustworthy antiseptic in all ages, differing entirely from simple solutions of formic aldehyde in nature and in action being much more powerful, devoid of any irritating properties, and which on solution by the saliva sets free that disinfectant in a nascent form."

INDICATIONS: in all conditions of **SEPTIC SORE THROAT,** as **TONSILLITIS**—Simple, Septic and Follicular—**DIPHTHERIA, SCARLET FEVER, MEASLES, THRUSH,** etc.

"In ten cases of **Diphtheria** the treatment by Formamint Tablets was employed as a substitute for local treatment by disinfectant gargles, and in some of the milder cases anti-toxin was dispensed with. In all cases the improvement was rapid."—(*British Medical Journal*, January 13th, 1906, Epitome, page 8.)

"A proved antiseptic and bactericide, non-toxic in action, far more efficient than gargles or mouth washes, particularly suitable for children and entails no pain, and its portability is of considerable convenience."—*Medical Magazine*, March, 1907).

Samples & Literature on Application to

A·WULFING & Co, 83, Upper Thames St, LONDON, E.C.

"APENTA"

THE BEST NATURAL APERIENT WATER.

" The predominance of Magnesium Sulphate and
" the presence of Lithium in **APENTA WATER** having been
" recently pointed out by **Professor Pouchet,** I determined
" to ascertain for myself the properties of this water, and
" for this purpose I prescribed it to a large number of my
" patients.

" My observations have proved that **APENTA WATER**
" is an **excellent, very active purgative,** and of **strictly**
" **constant composition.** Its action is **mild** and **reliable,**
" and a wineglassful or half a glass **acts** as an **aperient**
" **without producing either griping or discomfort.** It
" is the Water **specially suited** for the **treatment** of **habitual**
" **constipation.** Moreover, by its special and constant
" composition this Water **appears to me to merit a place**
" **by itself in the therapeutics of Mineral Waters.**"

Paris, 4th February, 1899.

HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin
with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

☞ Extremely useful in **Rickets, Scrofula, General Debility, Anæmia, Weak Heart, Neurasthenia,** and Convalescence from illness such as **Pneumonia** or **Influenza.**

☞ Unsurpassed as a **Strengthening Restorative in Diseases of the Lungs.** Has a very agreeable taste, and is taken with the utmost relish, even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

☞ **In prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered.** ☜

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - - Take from Half to One Teaspoonful twice a day in milk.
Children - „ One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.
Adults - - „ One Tablespoonful twice a day before the two principal meals.

☞ **SAMPLES AND LITERATURE,** *gratis and carriage paid, on application.*

NICOLAY & CO., 36 & 36a, ST. ANDREW'S HILL, LONDON, E.C.

AGENTS FOR NORTH AMERICA: LEHN & FINK, WILLIAM STREET, NEW YORK.

A SUBSTITUTE FOR COD-LIVER OIL.

WANDER'S DRY EXTRACT OF MALT

WITH IRON IODIDE.

This novel preparation of Iron Iodide is of NON-PERISHABLE character, and has the very unique advantage over older ones containing this salt in actually assisting digestion and assimilation, instead of impairing them. Owing to its rapid and easy assimilation this useful combination is THE BEST SUBSTITUTE FOR COD-LIVER OIL during warm weather, which it replaces successfully and over which it has the advantage of being readily accepted by the most fastidious patient.

SAMPLES TO MEDICAL MEN ON APPLICATION.

WANDER, Ph.D., Manufacturing Chemist, 1 Leonard St., City Rd., E.C.

THE ABSOLUTELY NON-IRRITANT LOCAL ANÆSTHETIC

Six times less toxic than Cocaine.
Increases the action of Suprarenin and other Adrenal Preparations.

NOVOCAIN.

Manufactured by the FARBWERKE vorm. MEISTER LUCIUS & BRUENING, Hoechst-on-Main.

NEUTRAL. EASILY SOLUBLE IN WATER. NOT DECOMPOSED BY BOILING.

Supplied in **Sterilised Solutions** or **Tablets** (with Suprarenin borate).

A.—For Infiltration Anæsthesia.
B.—Anæsthesia of Nerve Centres.
C.—For Medullary or Lumbar Anæsthesia.
E.—For Dental Purposes.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, JUNE 24, 1908. No. 26.

NOTES AND COMMENTS.

"Amazing Statues in the Strand."

THE bills of the evening papers last Friday in many cases contained as the *pièce de resistance* of their menu the words, "Amazing Statues in the Strand," and the eager public who crowded round the newsvendors were soon furnished with lurid tales of indecent statues erected outside—the *British Medical Association!* The sting of the tale lies in the element of truth it contains, and we confess we cannot conceive how the Council of the Association could have so lacked the element of humour as to have erected outside its new building statues which could only excite ribald remarks from the Strand urchins and pornographic references from Strand 'bus-drivers. We believe in art ourselves, and we are not totally averse from "the altogether"—in the proper time and season—but we cannot think that the buildings of the British Medical Association, facing into London's busiest street, constitute the most appropriate position for giving realistic demonstrations of the external genitalia of the human male figure. There are niches in the College of Surgeons' museum where such casts might be welcomed; there are art galleries (abroad) where similar exhibitions are not considered *outré*, but the Strand public is, perhaps, a little lacking in anatomical criticism and artistic perception, and the process of education might surely have been accomplished more gently. Moreover, if rumour speaks truly, what is now on view is nothing to what remains to be seen when the hoardings come down in Agar Street. To show that we are animated by no unfriendly feelings towards the Association, we are willing, on application by the secretary, to introduce him to an excellent stall in Covent Garden where fig-leaves are on sale at popular prices.

The Why and Wherefore of the Statuary.

FROM later information it appears that the designing of these figures was entrusted to a young and promising sculptor. The views of this artist with regard to the presentation of the anatomical facts commonly dealt with in the Temple of Æsculapius are not, to say the least of it, those that would secure the full approval of Mrs. Grundy. It is conceivable that nude figures of the kind might play a part in exterior mural decoration in all dignity and innocence, but, for all that, it is well to remember that even the ancient Greek sculptor found it desirable in many instances to cloak certain details with tracery. How he would have dealt with obstetrical complications we know not, but we fancy he would hardly have reproduced them in the way so boldly adopted by the Strand genius. The incident shows how necessary it is to keep unceasing vigil over those blameless gentlemen who sit on the Council, and to whose remissness in taste this extraordinary *gaucherie* is attributable.

Medical Longevity.

DR. T. L. HINTON, whose death at the age of a hundred took place last week, would be exceptional in any line of life, but he is almost phenomenal in a profession in which longevity is not a strong point. When the fact is recalled that Dr. Hinton not only passed a busy, active life, but that the best years of it were spent in India on active service or in camp, under hygienic conditions which would not be approved now, his constitution must be considered a marvellously good one. Sir Henry Pitman is, we believe, the only "centurion" left among us, and though he is a little senior to the late Dr. Hinton, his active life was passed in the more temperate climate and genial surroundings of the West End of London. It is encouraging to have these heroes of constitution to prove that there is some hope of the medical man outliving the meagre span apportioned to him by the Registrar-General, as the endless fumes and frets of practice often seem only worth enduring in view of a possible old age of retirement to contemplate the vista of a well-spent life. If the surly Atropos of Somerset House denies us even that solatium, many of the less successful members of the profession may feel inclined to have resort to the bare bodkin to end present discontents.

A New "Cure" for Consumption.

OUR enterprising contemporary *Tit-Bits* has presented to a startled world a new cure for consumption. The treatment recommended is lassoing. The intention is not, apparently, for the doctor to lasso the patient—that we could understand being an undeniable cure for the disease—but for the patient to lasso such objects of nature as fall within the range of his skill. The authority on whom our contemporary relies is Colonel W. F. Cody, better known to fame as "Buffalo Bill," who seems inclined to round off his adventurous career by imparting health to the ailing by this original plan. As mere medical men, we cannot conceive of any treatment less suited to the febrile stage of tuberculosis and more certain to excite hæmoptysis than riding bare-back on a horse and flinging the lasso far and wide, but we confess to never having tried the treatment ourselves, or having had the opportunity of watching its effects on others. "As at present advised," as the lawyers say, we can only express the opinion that nothing seems silly enough for people generally, and newspapers in particular, to say about consumption or cancer. It seems, indeed, that, having written all the rubbish they possibly can think of about these diseases, and written it over and over again, they are reduced to producing something palpably ridiculous, in the hope that no rival can say it is not their own original idea.

Wanted—an Entente Cordiale. In view of the Franco-British Exhibition and the new ties woven by the *entente cordiale,* we must accord a special welcome to a modest little announcement in *T.P.'s Weekly* which runs as follows:—

> To Doctors.—Parisian lady, middle aged, refined, intellectual, niece of well-known author, but with very small means, would give French conversation to doctor in exchange for medical attendance. (No. 1,083.)

As the great object of the practitioner's life is to avoid "conversation" on his rounds, the prospect of a daily discussion—carried on under the additional difficulty of an unwonted medium—does not strike us as very alluring, even when there is in prospect the sure reward which virtue holds out. The Parisian lady would, we fancy, need to be possessed of all the charm for which her race is famed to be able by this announcement to "draw" the most neglected of practitioners, and, at middle age, what can one expect? We are sorry for the lady, and we hope she may strike what she wants, but we cannot say we think the prospects are rosy. At any rate, there is a chance for any medical man who feels the obligations of international friendship to sit seriously on him. He has only to apply to No. 1,083.

Padgett, M.P. Dr. Pieron, of Paris, has lately been giving a dissertation on the psychology of lying, and, in accordance with the trend of modern criminology generally, his remarks go to prove that Padgett, M.P., is not a bad sort of fellow after all, and that his failing was not one of heart, but of failure of development of the ratiocinative faculty. This is a very cheerful and comforting doctrine, for there are few of us who have not at times been tempted to approach the border that demarcates fact from fiction, and now, on Dr. Pieron's authority, we may lay to our souls the flattering unction that it was not we, but an ontological perversion, that produced the shameful result. The old Adam appears to be a morbid embryological kink which our neurons assume independently of the will, and so we personally are blameless. The liar is born, not made. Let it not be thought, says the savant, that "lying is by any means the monopoly of women and children." The man may at any age up to fifty "kink"—through purely cerebral defect of course—into a "natural and spontaneous liar," a "brutal and malicious liar," a "psychopathic liar," or a mere "harmless liar." Images received on to the retina, in these morbid conditions, travel up the optic nerve to the brain, but at a certain junction, unconsciously, the image is switched off the original nerve line, and to the consciousness it presents a distorted idea. Thus, a camel may be duly focussed on to the retina in due proportion, but by the time that the brain has knowledge of it there may be three humps, a neck longer than a giraffe, a bright red hide, and pads three times their original size. No wonder the Pan-Anglicans are not all enthusiastic advocates of modern science.

LEADING ARTICLES.

THE KING EDWARD VII. HOSPITAL FUND, THE HOSPITALS, AND THE MEDICAL PROFESSION.

Like all other social institutions, the medical charities of the United Kingdom are being constantly subjected to the ordeals of an evolutionary discipline. In London the problems thrust in this way upon the attention of the public acquire a special importance from the magnitude of the philanthropic and charitable, as well as the economical and ethical, interests that are inseparably involved in the whole question of hospital administration. To some extent the existence of the great administrative funds affords a future promise of systematic organisation and co-ordination of the charities. That prospect, however, is at present somewhat deferred by the fact that the wealthiest and most powerful of those bodies, namely, the King Edward VII. Fund, is constituted on an absolutely autocratic and irresponsible basis. In other words, it is open to the Fund to make or mar the fortunes of medical charities by withholding grants, although it declines to state on what grounds such action is taken. The Council of the King Edward Fund, therefore, is in this sense a summary court wielding enormous power, but whose decisions are subject to no appeal, and whose constitution, being non-elective and non-representative of the interests concerned, is absolutely beyond popular control. We decline to believe that any such constitution, foreign as it is to the genius of the British nation, can be permanently maintained on these lines. As things stand, the fate of individual medical charities of the metropolis may be decided by the whims and the caprice of persons whose only claim to confidence may be that they happen to have been placed on the Council of the Fund. The policy of extermination of the smaller hospitals is tacitly adopted, for example, and from that moment is straightway put into force at all costs. By the power of the purse the Fund practically forces amalgamation upon groups of smaller institutions, regardless of the fact that in not a few cases members of the individual medical staff are deprived of their appointments in the newly-constituted collective bodies. Hampstead affords a peculiarly typical and instructive example of this high-handed procedure. The general practitioners of that district had organised and efficiently staffed a local hospital. The King Edward Fund insisted on amalgamation with a hospital in a neighbouring parish. The original staff lost their appointments, excepting two who were permitted to remain for a limited period, and a fresh staff was selected from consultants elsewhere. The Fund accepted the nomination in several instances of surgeons and physicians who were pluralists in various directions. Some of them, at least, hold so many other appointments that it is difficult to see how they could hope to do justice to their new duties at Hampstead. We wonder if the question of pluralism in hospital appointments has ever been considered carefully by the King Edward Fund. If not, can they defend any policy in which pluralism is concerned? If so, why should not the Fund openly declare its policy so that the lay and medical community may know on what lines the grants of the Fund and the interests of the sick public and of the medical profession are being dealt with? While the Fund declines to state the grounds of its action in this or that given direction, it will be impossible to maintain the confidence of the public indefinitely. If the policy of the Fund be sound, and its motives and impartiality above suspicion, why should it decline to make a public declaration of its principles, to explain and justify its decisions, and to permit an appeal where any complaint is made of individual injustice or unfairness? Above all, why should any great public body dread the wholesome discipline of public representative control? There is another pertinent point to which attention of the authorities of the Fund may be drawn. In one, at least, of the amalgamations that have taken place under their auspices the amalgamated hospital has been permitted to exclude holders of Scotch and Irish qualifications from appointments of the honorary medical staff. We allude to the Orthopædic Hospitals, in two out of three of which Scotch and Irish diplomates were admitted to the staff, but are excluded in the new or amalgamated institution. Can the King Edward Fund seriously defend this exclusion of legally qualified medical men from these posts? As the Fund enforces its will in so many directions, it could surely interfere to prevent the perpetration of an injustice of this kind. We beg further to draw the attention of the King Edward Fund to a recent meeting of the Irish Graduates' and Scotch Diplomates' Associations, whereat the action of the Miller Hospital at Greenwich in advertising for a surgeon with an English fellowship qualification was called in question. The advertisement was inserted in the *Times*, and the public thereby informed of the disabilities attached by the Miller Hospital to surgeons whose education, although carried out on lines administered by the State, was conducted in a Scotch or Irish school. Further, we invite the attention of the Fund to a statement, which may or may not be correct, that the Board of the Miller Hospital has the power to frame rules to fit particular cases without consulting governors. If the King Edward Fund assumes the post of *censor morum* of the London hospitals, the Miller Hospital appears to demand some share of its criticism. We believe that some years ago the Miller Hospital enjoyed the distinction of spending more money per patient than any other charitable institution in the metropolis. A wholly unnecessary advertisement in the *Times* certainly does not lend the impression of economical management. Why should the Board want to advertise outside the medical journals, unless, indeed, it be to emphasise the fact that no Scotch or Irish need apply. In the points thus raised, namely, the nature and cost of advertisements, the exclusion of legally-qualified British medical men from hospital appointments, medical pluralism, and the inherent rights of the small hospitals, we venture to think that the King Edward Fund will find a legitimate field of activity which will in the long run tend to place the sacred cause of medical charity on a sounder basis than is likely to be attained by the irresponsible administration of a well-meaning and honourable, but, at the same time, an autocratic and unrepresentative body. In making these criticisms it is hardly necessary to say that the motives of the King Edward Fund are transparently high and noble, but we feel it, nevertheless, our duty to review the situation, in the hope of consolidating this great body in the confidence of the community.

An epidemic of small-pox at Woolsthorpe-Belvoir, Lincs., originated with a soldier who had been discharged from a transport ship at Southampton. His removal into the district was not notified by the War Office, who have now expressed regret. The outbreak cost the district between £400 and £500.

CURRENT TOPICS.

An Army Nursing Organisation.

The attempt of the present Government to reorganise our Army system is, at any rate, comprehensive. Amongst various excellent non-combatant features connected with the Territorial force, one of the most important is the organisation of a Nursing Service in connection with its general hospitals. This step has been taken by the Army Council, which has decided to establish an Advisory Council in connection with this branch of administration. It is formally announced that this Advisory Council will frame rules for the admission of nurses into the Army Service, and make such recommendations as may seem necessary for the administration of the Service and for the appointment of matrons, sisters and nurses thereto. Her Majesty the Queen has graciously consented to become President of the Nursing Service, and has further approved the appointment of the Duchess of Montrose as Vice-President. The Advisory Council is under the chairmanship of Surgeon-General Sir Alfred Keogh, K.C.P., Director-General of the Army Medical Service. Its members include, amongst other, the Countess of Derby, the Countess of Jersey, Lady Grenfell, Miss Haldane, Miss Cox-Davies, matron of the Royal Free Hospital, and the matrons of four other hospitals and of a well-known institute for nurses. The secretary is Miss Sidney Browne, R.R.C. It may be noted that not a single one of the matrons is married, an observation that applies to most women who attain the prizes of the nursing profession in our great hospitals. Speaking generally, the institution of a proper nursing organisation for our new Territorial Army is a matter for congratulation. From the medical point of view, it is the duty of the State to tend the sick and wounded soldier with all the resources of modern medical science. It is only by preparation in time of peace that a proper equipment can be rendered available in time of war. The failure of the nursing service in the South African War was one of the most terrible features of the collapse of the Army medical organisation in that campaign. It is to be hoped and believed that the establishment of an efficient nursing service by the Army Council marks the passing of the old order of things with regard to the sick and wounded British soldier.

Mumps in the Navy.

The news of an unusual outbreak of epidemic disease has come from Portsmouth. The whole of the ship's company of H.M.S. *Nelson*, the training depôt for naval stokers, numbering 800, has been transferred by water to Haslar, where they are encamped outside the Naval Hospital. A careful daily inspection by the hospital medical staff last week resulted in the daily discovery of some ten to fifteen or twenty cases of mumps. There are about 2,000 sailors at the Royal Naval Barracks depôt, which has become involved in the outbreak by the appearance of several cases. The outbreak, it need hardly be remarked, is of an exceptional kind, as the disease is usually confined to children and young persons. Considering the marked characters of this common and obviously specific infection, it is not a little curious that its origin should be wrapped in complete mystery. No clue, for instance, has been obtained as to the reason why the brunt of the early inflammatory disturbances should fall upon the parotid and the sub-maxillary glands. Nor has the metastatic orchitis which so frequently follows the subsidence of the parotitis, been any more satisfactorily accounted for. On the whole, mumps may be said to offer a fine field for the collective medical investigation which is fast becoming a fixed feature in modern research. At the same time, it must be borne in mind that a similar obscurity of origin is shared by such familiar zymotic affections as whooping-cough, measles, and small-pox, the results of which are far more serious than that of the comparatively innocuous mumps. There is something almost ludicrous in the spectacle of the fighting-men of a great naval station being laid low by this schoolboy's malady. Some consolation is to be derived from the fact that one attack, as a rule, confers lasting immunity against the disease. At present there is a good opportunity for the study of this interesting complaint open to the scientific enthusiasts of the Navy Medical Department. Why should not Government make a special grant for such an investigation?

Infectious Disease and Examinations.

THE annals of modern high standard examinations, could they be even approximately written, would probably furnish an abundance of diverting reading. An incident in the recent Natural Science Tripos examination at Cambridge furnishes a case in point, although the University dons may take a different view of the matter. When Part II. of the famous examination became due, it was found that a certain famous Welsh scholar was suffering from an infectious disease, the precise nature of which has not been announced. As this brilliant undergraduate had already obtained the highest honours in Part I., it looked as if his chances of distinction had been suddenly extinguished by the hand of Providence. Obviously, it was out of the question that the sufferer should be permitted to take his place among his fellow students at the examination. We are glad to say that in this particular instance the somewhat conservative University authority rose to the occasion. A special room was provided and the patient conveyed thither in charge of a nurse, who remained with him all day, and administered stimulants to him at intervals, and at the end of the examination he was taken back to bed. As a result the invalid attained an honourable position in Class II. The precedent thus established may conceivably give rise to some amount of trouble in various quarters. The non-isolated and unstimulated examinees, for instance, may claim that they were placed at a disadvantage as compared with their sick rival. The principle is clearly capable of wide extension, and in some instances a good deal of individual disaster might be averted, for many a brilliant competitor has been thrown out of the struggle by the advent of sudden sickness.

A Schism among the Dentists.

THE penal clauses of the Dentists Act of 1878, like those of the Medical Acts, are almost complete failures. They were devised with the object of enabling the public to distinguish between the legally qualified practitioners and the uneducated pretenders, and they are, in fact, entirely ineffective in preventing ignorant and fraudulent impostors from palming themselves off as legitimate professional men. The British Dental Association, presumably with the best legal advice, has striven to establish the power of the law as suggested by the spirit of the Act, and has virtually failed. It is quite evident that prevention of grossly illegal dental practice will not be possible without amendment of the law. If this amendment is to be brought about, it will be first of all necessary to prove to the satisfaction of Parliament, or, at least, of the responsible statesmen, that reform is called for in the interests of the public as much as, or more than, for the advantage of the profession. The weakness of the law has been sufficiently demonstrated. The hope of reform lies in concentration of the whole forces of the profession to the task of establishing their case. If this cannot be done through the medium of the British Dental Association, which includes the great bulk of those having valid claim to authority and professional distinction, the case is hopeless. The proper course for those dissatisfied with the present state of things is to add their forces to the Association, and press forward the preliminary movements towards reform. Any attempt to establish a new society acting without the concert of the Association, in antagonism to it, will do nothing but injury to the cause, the promotion of which is so rightly desired

The Government and Tuberculosis.

LAST week the Chief Secretary for Ireland brought in his promised Bill dealing with the Prevention of Tuberculosis in Ireland. The provisions of the Bill are in the directions of reform which we have frequently suggested. They fall under three heads—Notification and Disinfection, Hospitals and Dispensaries, and Sanitary. In the first place tuberculosis is made, under conditions to be laid down by the Local Government Board, a compulsorily notifiable disease. For failure to notify a medical man will be liable to a fine not exceeding forty shillings, and for each certificate of notification he will receive a fee of one shilling if the patient be in a public institution, or of two shillings and sixpence, if anywhere else. As to the provision of hospitals and dispensaries, county councils are empowered now, for the first time, to erect and maintain such institutions. Several important clauses are classed as "Sanitary." Sanitary authorities are to have power to provide and pay for courses of lectures in their districts, and to appoint bacteriologists for the examination of meat, milk, sputum, or pathological specimens. Medical officers of health and other authorised officers are to have power to take samples of milk or milk products produced or offered for sale in their districts. The Bill seems to us a thoroughly useful one, and we hope it may find its way to the Statute Book.

Research Defence Society.

THE inaugural meeting of the Research Defence Society was held on the 19th instant at the rooms of the Royal Society of Medicine, London. There was a large and enthusiastic attendance of members, who followed with attention the temperate and closely reasoned speech of the President, Lord Cromer. He said they must agree to differ from those who held the extreme view that it was not under any circumstances justifiable to destroy animal life. The full application of that theory would, in his opinion, carry us to some very strange and practically impossible conclusions. It required no special knowledge to be convinced that well nigh every advance in medical science since Harvey discovered the circulation of the blood has been, directly or indirectly, the result of experiments on living animals. One modern example was the discovery of the transmission of malaria by mosquitos, whereby it was aptly said the Tropics were going to be made habitable. Malta fever was another case in point. Fever, again had been banished from Ismailia, on the Suez Canal, a place that was formerly nearly uninhabitable, by the use of knowledge gained from vivisection. If the cause of cancer were discovered, he ventured to say, it would be by way of experimental research. He denied the assertion of those who attributed a wanton infliction of pain by experimentalists. A resolution by Sir Thomas Barlow was then carried unanimously:—"That the Research Defence Society be, and is hereby constituted, to make generally known the facts about experiments on animals in this country, and the regulations under which they are conducted, the immense importance of such experiments to the welfare of mankind, and the great saving of human life and health which is already due to them."

St. Bartholomew's Hospital.

ANYTHING which transpires in connection with the internal affairs of an important charity like St. Bartholomew's Hospital cannot fail to attract universal attention. It is true that in view of its rich endowment this hospital does not require to appeal to the public for its maintenance. Despite this fact, as a charity it is still amenable to the laws of the realm, applicable to the administration and control of charitable funds. From this point of view, then, the announcement that the Treasurer and five Almoners of the Hospital, that is to say, the working committee of the Governors, who are responsible for the administration and management of the great charity, have tendered their resignations, in consequence of a failure of agreement with the general body of governors, calls for more than a passing notice. So far the governors have not taken the public into their confidence in respect to the grounds upon which this disagreement is based. It is stated that the Treasurer and Almoners unanimously recommended a certain policy, of which the governors have seen fit to disapprove. In other words, those who from their position must know what is best for the hospital have been over-ruled by those who have merely a voting interest in its concerns. We cannot believe that a *contretemps* of this kind can have any other than a harmful effect upon the charity, even although it happens to occupy the commanding independent position of that of St. Bartholomew's. The incident clearly shows that, unique as it is in the history of the Hospital, something must have occurred to disturb the harmony and orderly working among those who are responsible for its administration, which calls for public notice. The governors, no doubt, were fully aware, in casting their adverse vote, what the result would be, and yet, despite this, they apparently did not shrink from recording their verdict. That verdict, naturally, carried with it a moral vote of censure upon the managing committee, who immediately adopted the only course open to them of tendering their resignations—which have been accepted—and there the matter stands for the present.

PERSONAL.

H.M. THE KING has conferred the Honorary Commandership of the Royal Victorian Order on Dr. Eugène Botkine, Physician-in-Ordinary to the Czar.

HIS MAJESTY THE KING laid the foundation-stone of the new King Edward VII.'s Hospital at Windsor. The cost of the building will be about £20,000, of which £12,000 have been already subscribed, including the King's present and previous donations.

THE BISHOP OF LONDON will preside at the annual distribution of prizes at St. Mary's Hospital Medical School, Paddington, on Monday next, June 29th, at 3 p.m.

DR. KITAZATO, who has just been elected a Fellow of the Royal Society, is the first Japanese to gain that distinction.

THE third Norman Kerr Memorial Lecture will be delivered by Dr. Taav Laitinen, Professor of Hygiene in the University of Helsingfors, and Director of its Hygienic Institute. He has selected as his subject "The Influence of Alcohol on Immunity."

DR. RAYMOND, Physician to the Salpêtrière Hospital, Paris, delivered an address in the library of the Royal College of Physicians of London on Monday last, June 22nd.

SIR JAMES SAWYER will take the chair at the dinner of the provincial meeting of the Society for the Study of Disease in Children.

SURGEON-GENERAL G. J. H. EVATT, C.B., will take the chair at the annual meeting of the Poor-Law Officers' Association, to be held at Hull on July 15th.

SURGEON-GENERAL W. L. GUBBINS, C.B., M.V.O., Principal Medical Officer of the King's Forces in India, has been appointed Deputy-Director-General of the Army Medical Service at the War Office, in place of Surgeon-General Fawcett, C.B., who is retiring.

THE EARL OF CREWE will unveil the statue of Her Majesty Queen Alexandra at the London Hospital, on Friday, July 10th, at 4 p.m. The annual prize distribution to the students and probationers of the Medical College attached will take place at 3.30 on the same afternoon.

LORD ROTHSCHILD has consented to distribute the medals and prizes gained by students at Guy's Hospital during the past winter and summer sessions, on Wednesday, July 8th, at 3.15 p.m., when the Governors and medical staff will give a garden party in the grounds of the hospital.

A CONGRESS of French medical practitioners, the second of its kind, is to be held at Lille from the 25th to the 28th inst. The members intend to come to London on the 30th inst., and remain till July 2nd. On the afternoon of Wednesday, July 1st, they are to be received by the Lord Mayor and the Lady Mayoress at the Mansion House.

PROBABLY no ambulance competition in South Wales has evoked such widespread interest as that which took place at Mardy, in the Rhondda Fach, on June 13th, for General Sir Charles Warren's Rhondda Ambulance Challenge Shield, which, by the narrow margin of one point, the local team succeeded in retaining for the coming year—an achievement which reflects the greatest credit upon the instructor, Dr. Glanville Morris.

LORD RAYLEIGH, as Chancellor of the University of Cambridge, on June 16th, performed his first official act by opening the new wing of the Cavendish Laboratory, which Lord Rayleigh, as a Nobel prizeman, presented to the University. The ceremony was interesting because it occurred upon the anniversary of the opening of the original Cavendish Laboratory, which the University owed to the generosity of the seventh Duke of Devonshire, who was Chancellor in 1874.

ON June 13th, Surgeon-Colonel Edward Hopkins, of Llandilo, was presented by the inhabitants of the district with a life-size oil painting of himself and other gifts "in recognition of the valuable medical services which he has so readily and gratuitously rendered for a great number of years." The painting shows the surgeon wearing his old A.M.D. uniform and six campaign medals.

DR. G. JUBB and Dr. R. Lawrence, have been appointed assistants to the County Medical Officer of Health, Cheshire, to devote their whole time to the inspection of children in attendance at elementary schools in the county elementary education area, at a salary of £350 each per annum and travelling expenses.

A CLINICAL LECTURE

ON

SCIATICA.

By ROBERT A. FLEMING, M.A., M.D., F.R.C.P.Ed.,

Physician to the Edinburgh Royal Infirmary, Lecturer on the Principles and Practice of Medicine in the Edinburgh Medical School, Examiner in Medicine, Aberdeen University.

I HAVE selected as a subject for this clinical lecture a very common ailment, and yet one which presents many difficulties both as regards the diagnosis of the cause of the sciatic pain and also the treatment which should be adopted in different cases. We constantly meet with patients in hospital and private practice who are suffering from sciatica. The ailment in many of these cases yields readily to ordinary anti-rheumatic or anti-gouty remedies; and yet there remains a quite considerable proportion of patients whose sciatica is not relieved in the smallest degree by such treatment, and whose affection tests our skill and patience to the utmost. I do not imply that none of these intractable cases are rheumatic or gouty in causation, but merely that they prove intractable to the ordinary line of treatment.

I propose to divide sciatica into three groups, and to try to differentiate these three groups or types as sharply as possible when describing the etiology and the clinical features of each group. If you keep before your minds these three distinctive types, then the treatment suitable for each will become clear.

ETIOLOGY.

Type I.—In this type I include all cases of interstitial neuritis and perineuritis, the involvement of the actual nerve fibres being generally secondary where they are involved at all. There is a history of exposure to wet or cold, or both, and the subject is usually of rheumatic tendency. Both sexes suffer, but men, from the nature of their work, supply a larger number of cases than women. The age is generally from puberty to the end of middle life. Rheumatism is the commonest cause of this type of sciatica, and, in fact, it is the chief cause of sciatic pain taking all the varieties together. Another group of cases belonging to this type are due to gout, and occur in gouty individuals who have broken some of the canons laid down by their medical advisers, and have probably, in addition, exposed the region of the sciatic nerve to cold or wet. Syphilitic neuritis also occurs, but it is rare, and diphtheritic neuritis, which differs from syphilitic inasmuch as it is generally parenchymatous, while the latter is interstitial, is also of comparatively infrequent occurrence.

It should be added that if an individual of rheumatic tendency is exposed to wet and cold, any local injury or pressure exerted on the sciatic nerve may aid in the production of the sciatica, and may determine the side to be affected.

Type II.—There is sciatic neuralgia, which is not due to any of the causes referred to under the first type, and which may occur apart from any tumour or other cause of pressure on the nerve or nerve roots of the sacral plexus, referred to under the third type of sciatica. The causes of neuralgia elsewhere produce sciatic neuralgia, although it must be admitted that a pelvic tumour such as a carcinoma may both cause sciatic pain by pressing on or infiltrating the nerve or nerve roots, and may also be directly responsible for a truly reflex neuralgic pain.

Type III.—Pressure on the sciatic nerve or on the roots of the sacral plexus causes sciatic pain. A familiar instance of such pain is common in advanced stages of pregnancy, when the uterine tumour presses on the nerve or nerve roots and causes pain which radiates down the nerve. A loaded bowel is sometimes responsible for sciatic pain more commonly on the left side, and any pelvic tumour such as a large uterine fibroid, or mass of glands as in lymphadenoma, may give rise to severe pain in the line of the sciatic nerve.

Hip-joint disease and rheumatoid affections of the spinal column have been held responsible, not merely for pain which might be mistaken for sciatica, but for the secondary development of true sciatica either a true neuritis of interstitial nature (Type I.) or a sciatic neuralgia (Type II.).

PATHOLOGICAL ANATOMY.

The inflammation is usually *interstitial*. It may specially involve the outer sheath of the nerve—a *perineuritis*, or it may affect the sheaths of the individual funiculi, or even the interstitial tissue inside the funiculi. The nerve is believed to be reddened or congested in acute cases, and is certainly swollen. The important points to remember are that wherever the inflammation may be, there is effusion of inflammatory lymph, and that that lymph cannot readily find exit and is slowly absorbed if in large amount. Where a serious intra-funicular effusion has occurred, atrophy of nerve fibres may follow and the functions of the nerve fibres may be interfered with at least temporarily. In this way wasting of muscles, areas of anæsthesia, and even trophic changes in the skin result. It is not necessary here to enter into a full description of Wallerian degeneration, or the pathological changes which may ensue in muscles, skin, and in the cell centres of the affected neurones; but it is easy to understand that a large effusion, if not absorbed or got rid of in some way, must in time lead to formation of connective tissue, and this will press on nerve fibres in a way which cannot easily be removed. Herpes occasionally develops in the line of the affected sciatic, but is rare.

There is no known pathological change in pure cases of neuralgia (Type II.) or where pressure merely induces pain and does not abrogate the functions of the nerve fibres nothing may be noted (Type III.).

THE CLINICAL FEATURES.

Type I.—*Interstitial and Perineuritis.*—In the simplest case a patient, predisposed to rheumatism, sits on damp grass or gets wet and chilled and develops sciatica. The pain is dull and aching, gradually becoming more severe, and rarely is it sharp or lancinating. It is generally constant, but may become worse at night, or may be paroxysmal in its mode of harassing the patient. The patient cannot sit, especially on a hard seat, except in an attitude that enables him to avoid all pressure on the buttock of the affected side. The pain shoots down to the knee or to the heel, and is often worst at night when he gets warm in bed. He cannot stoop so as to touch his toes, and if the nerve is very susceptible to pressure he limps with the affected leg. In a severe case he can neither straighten his leg nor can he bend it fully, because the pressure of the muscles on the nerve and the slightest stretching of the nerve are exquisitely painful. He walks on tiptoe by preference, and if the neuritis progresses still further he may become completely bedridden. It is most important to remember that sciatica is almost always unilateral. Bilateral sciatic pain should suggest a lesion of the nerve roots, or a lesion of the cauda equina.

There are certain painful points, described originally by Valleix. Those are situated (1) above the hip-joint; (2) at the sciatic notch; (3) about the middle of the thigh; (4) behind the knee; (5) just below and behind the head of the fibula; (6) behind the external malleolus; and (7) over the dorsum of the foot. They are certainly more commonly present in cases of neuralgia (Type II.), but are by no means absent in severe cases of neuritis. Cramps in the calf and other muscles may occur in bad cases, and there is sometimes a degree of pyrexia, but it is exceptional and only probably appears as an early manifestation.

On physical examination the nerve may be demonstrated to be painful to pressure between the sciatic notch (situated midway between the ischial tuber and the great trochanter of the femur) and the popliteal space, while areas of anæsthesia (outer side of leg below the knee, etc.) are not infrequently present where the exudate has damaged the conductivity of the sensory neurones. The muscles may become flabby and very marked wasting with fibrillary contractions may develop where motor neurones are involved. In cases of such gravity, formication and numbness may eventually be found, and even the reaction of degeneration on testing the affected muscles, but the latter is rare.

In some patients the small sciatic is specially involved or some other branch of the lumbo-sacral plexus, and it is probable that where Type I. has developed, Type II. or in other words a secondary neuralgia may be superadded.

Even mild cases are apt to relapse, and a sudden strain, over-exertion, or chill may cause another attack, often more severe than the first. In any case the pain usually passes off gradually. Severe cases with anæsthesia and wasting of muscles will certainly cripple the patient for months, and may even result in permanent deformity such as spinal curvature.

Herpetic eruptions sometimes develop along the line of the sciatic nerve and its branches.

Type II.—*Neuralgia of the Sciatic Nerve.*—Where the neuralgia is not merely superadded to cases included under Types I. and III. the clinical picture is fairly sharp and distinctive. The patient has been subject to neuralgic pains elsewhere, and very probably at the same time as he complains of his sciatic pain the 5th cranial nerve or some other cranial or spinal nerve may also be affected. The painful points of Valleix, one or more, are often the chief sites of pain, and other parts of the nerve and its branches are not tender to the touch. There is no anæsthetic area and no evidence of any wasting of muscles. The pain of neuralgia is typically periodic, and it does not shoot down to the knee or to the heel as it so commonly does in Type I. Lastly, it is rare to find the patient limp when walking.

Before leaving the description of this type may I again remind you that a neuralgia may be secondary to a neuritis or to a pelvic neoplasm, etc., and so it is by no means always possible to differentiate our cases of sciatic pain as I am trying to do here.

Type III.—*Sciatic Pain due to Pressure.*—Here there is often no difficulty in recognising the tumour or whatever is causing pressure after a careful abdominal, rectal or vaginal examination. The pain may shoot down the nerve, but the nerve itself is not, as a rule, tender to the touch, and walking or anything which increases the pressure of the muscles on the nerve in the thigh rarely increases the discomfort. Unless a secondary neuralgia has been set up there is no evidence of the existence of the painful points of Valleix.

DIAGNOSIS.

In hip-joint disease, pressure on the head of the femur and forcing it against the acetabulum causes severe pain, and where the *sacro-iliac synchondrosis* is at fault, pressure exercised on the iliac crests so as to force them against the sacrum increases the pain. In affections of the *cauda equina* the sciatic pain is usually bilateral, and similarly, if there is an extensive bilateral lesion of the *lumbo-sacral plexus,* the pain is not so local and distinctive. Bilateral sciatica is rare, and should always suggest a cause which is situated higher up than the sciatic nerve.

PROGNOSIS.

Severe intractable cases are very difficult to speak of with enthusiasm, but I believe much can be done to prevent cases becoming chronic and intractable.

TREATMENT.

I do not purpose describing the treatment appropriate for neuralgic cases (Type II.) or pressure cases (Type III.), but wish to devote a few minutes to a *résumé* of treatment applicable for cases which belong to the first of our types.

Most ordinary cases of sciatica yield to large doses of *sodium salicylate* and *sodium bicarbonate,* but it is essential in every case which is not of the most trivial character to remember the inflammatory exudate and order *physical rest* for the limb, and even the use of a long splint, if the patient can tolerate it. Wrap the limb up in cotton wool and apply methyl salicylate or some more vigorous counter-irritant, such as the linimentum terebinthinæ aceticum, fly-blisters (along the line of the nerve), or the actual cautery. Rest is the main thing, the exact method of local counter-irritation being of less importance. Hot-air baths of the Greville type are also useful, the hot air being applied to the limb locally, and a temperature of 200° to 300° F. may be attained.

When there is a more severe case to be treated I believe in *acupuncture.* At least half-a-dozen sterilised needles should be inserted into the nerve, the highest close to the gluteal fold and the lowest well above the popliteal space. A double row of needles is better than a single, and, dexterously inserted, the patient should not be aware of more than the first three. The line of the nerve should be carefully marked with ink before beginning the operation. Leave the needles in position for half to one hour, keeping the patient lying flat on his face or on his unaffected side, with a cage over the legs and of course well covered with bedclothes. Relief is prompt, but several insertions may be necessary. Benefit depends almost certainly upon the escape of exudate from the swollen nerve sheath.

Injections into or near the nerve are sometimes used. 80 per cent. alcohol and 1 to 2 per cent. osmic acid injected into the nerve should never be used on any consideration. They may do much damage to the myelinated nerve fibres, and are dangerous remedies. Various strengths of eucain or cocaine in saline solution have been recommended, and are preferable. Schleich and Lange were among the first to advise large injections of saline solution into the nerve, and both used B. eucain (1 in 1,000 of 8 per cent. salt solution). Similar injections have been recommended, only of larger bulk, into the tissues round the nerve and specially into any painful area. It is thought that the solution by its bulk (100 or more c.c.'s) may tear away or separate nerve endings, and so arrest pain. Injections of sterilised air into the painful areas have also been much used. Half a litre of atmospheric air, sterilised by being passed through antiseptic wool, is injected under the skin and around the nerve: Cordier succeeded in 23 out of 25 cases, but others have not been so fortunate with this procedure.

Electrical treatment I have found disappointing. I think high frequency and galvanism have given me the best results, but there is no feeling of certainty as to the result being even temporary benefit, and I should never hesitate in choosing between acupuncture and electricity, to prefer the former. Of baths I might say much. All spas where rheumatism and gout are treated successfully are well worth a trial. Mud baths, the hot under-current douche, and a combination of hot baths with very carefully applied massage will be found most efficacious. Gouty patients, and, of course, the much less common cases of syphilitic origin, should be treated on constitutional lines.

Of *surgical treatment* for sciatica it is not possible in the time at my disposal to speak. If there are adhesions then separation of these adhesions does good, but are there often adhesions? Nerve-stretching and excision of a portion of the nerve are serious operations and may not lead to definite and certain recovery, therefore they should not be lightly undertaken. Where nerve-stretching is employed the limb may be lifted off the table by the sciatic nerve, and this is thought to cause the breaking down of adhesions, to which the pain is due. It certainly seems probable that in a very long-standing case of inflammation of the sheath of the nerve, adhesions might form, and if so nothing short of dissection or stretching can break such adhesions down Possibly fibrolysin, which is said to be so efficacious for the removal of pathological fibrous tissue, might be tried before resorting to operation, but I have no personal successes with this remedy to report. If care is taken, however, with the early treatment of sciaticas, such cases should be very much more uncommon than they are.

I have merely been able to summarise a few of the methods of treatment, and have not discussed the treatment of neuralgia or pressure siaticas, but if I have succeeded in giving you a better understanding of the causation and the clinical features of a somewhat difficult subject my labour will not be entirely in vain.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by T. Percy C. Kirkpatrick, M.D., F.R.C.P.I., Physician to Steevens' Hospital, Dublin. Subject: "On the Physical Examination of the Stomach."*

ORIGINAL PAPERS.

SOME CASES OF GALL-STONE SURGERY. (a)

By DENIS KENNEDY, F.R.C.S.I.,

Surgeon to Jervis Street Hospital, and to the Children's Hospital, Dublin.

In the present contribution I wish to bring under your notice some cases of gall-stone surgery. In no branch of our profession has more progress been made in the last decade than in the surgery of the gall-bladder and bile ducts. An important factor in this progress has been the recognition of the fact, by physicians as well as surgeons, that drugs have not the slightest influence in dissolving a biliary calculus before its exit from the body, or in dislodging it from the position it may occupy in any part of the biliary tract. And drugs have just as little influence over the many grave and pathological lesions that may ensue from gall-stones. Consequently, although the physician has his part to fulfil in the early recognition of the disease and in the general guidance of the patient, the treatment of the disease itself, as well as of the sequelæ that may ensue, belongs entirely to the surgeon. Of course, no one can deny that many patients carry their gall-stones with them to the grave, and that their life has not been materially shortened nor made too unpleasant by their presence. Others, again, get rid of a large number of gall-stones, when Nature is aided in her expulsive efforts by the improved vigour and tone which the system receives when a time is spent at some of the popular health resorts, such as Carlsbad. But these must be looked on as exceptions to the ordinary course of events which accompany the presence of gall-stones in the biliary tract.

A statement is frequently made that gall-stones may be present in the gall-bladder without giving rise to any symptoms. I think this is rarely true. There may be no symptoms which point directly to gall-stones, but stomach troubles are nearly invariably present, due to the pathological lesions that follow the presence of biliary calculi when they remain for any time in the gall-bladder or bile ducts.

These pathological changes consist essentially in the formation of adhesions between the viscera in the upper and right side of the abdomen. The pyloric end of the stomach, the colon, the gall-bladder, and liver are found matted together by dense adhesions. Consequently, when food is being passed through the pylorus, which is narrowed and inflamed on account of the adhesions, pain is experienced resembling that due to gastric ulcer. And I have met many cases that were treated for years for stomach trouble, especially for ulceration, when the primary and essential disease was the presence of calculi in the gall-bladder. A typical example is the following case:—

Mr. G., æt. about 45, I saw in February, 1906, in consultation with Dr. Cox. For 15 years he was dieted and doctored for stomach trouble, and labelled "chronic dyspepsia." He travelled twice round the world, and wintered abroad for years, in the endeavour to get health. In spite of this he was sometimes bad, sometimes better, but never well. Occasionally he got rather bad attacks of abdominal pain, which were always attributed to some indiscretion in diet. For a couple of years previous to my seeing him these attacks became more and more frequent, and rendered his life miserable. On examination, all I had to do was to confirm the diagnosis of gall-stones already made by Dr. Cox, and to agree to carry out operative treatment recommended by him. On operation, I found the viscera matted together in the upper abdomen, the gall-bladder full almost to bursting point with calculi. On opening the gall-bladder I removed hundreds of small black calculi resembling particles of coal in appearance. I provided for free drainage from the gall-bladder, and the patient made a rapid and complete recovery. He has since remained in perfect health, gained a few stone in weight, can eat what he likes, and never knows he has a stomach.

A much more serious condition of things that we have frequently to deal with is when the calculus or calculi become lodged in the common bile duct. The symptoms that such a condition give rise to are, as a rule, definite, and not very difficult to diagnose. Jaundice and its associated symptoms will be more or less pronounced according to the degree of obstruction produced in the duct. Pain is usually present, but not necessarily severe; wasting of the patient occurs, and most intense irritation of the skin and eyes are also usually present. But probably the most significant set of symptoms are attacks, ague-like in character, from which the patient is prone to suffer. These attacks are said to be due to either a catarrhal or suppurative inflammation, occurring in the gall-bladder and bile ducts above the obstruction. They may, however, be completely absent, especially when the common bile duct is completely occluded. It is then more difficult for the infection to travel upwards from the intestine. Such a case is the following:—

Mrs. S., æt. 52, consulted me in October, 1905. Her history was as follows:—Four years previous she got an attack of abdominal pain, lasting with remissions for three days. It then passed off. Six months subsequently she got a second attack; the pain lasted two days; she then became jaundiced, and continued so. On examination, the patient was deeply jaundiced, looked emaciated, and complained of feeling very languid and weak. She also suffered from considerable irritation of the skin and eyes. There seems to have been a complete absence of any febrile attacks, or of rigor. She suffered no pain. The liver was apparently enlarged, reaching down below the umbilicus; there had been no hæmorrhages, nor any vomiting. I diagnosed obstruction of the common bile duct by a calculus, and recommended operation, which I subsequently carried out. On opening the abdomen by an incision through the right rectus muscle, I found the liver very enlarged, but had the greatest difficulty in finding the gall-bladder, on account of the dense adhesions that were present. The viscera were matted together as if with malignant growth. The gall-bladder was atrophied and contained neither bile mucus nor calculus. With considerable difficulty I exposed the common bile duct and palpated a calculus just as duct passes behind the duodenum. I incised the duct and removed a stone, which measures 2 in. in circumference and weighs 55 gr. I stitched a drainage tube into the cut bile duct in order to afford free drainage. A couple of iodoform strips placed down to the incision in the duct and surrounding the drainage tube completed the operation, which lasted one hour and 50 minutes. The exposing of the gall-bladder and bile ducts through the dense adhesions was the sole cause of the prolonged time necessary. Convalescence was uninterrupted; the patient left hospital five weeks subsequently, completely well, and she has remained so since.

(a) Paper read at the Surgical Section of the Royal Academy of Medicine in Ireland, March 25th, 1908.

A most interesting case is one that came under my care last July. She then had perforation of the gall-bladder, and I subsequently had an operation for occlusion of the common bile duct by calculi. The history of the case is as follows:—

Mrs. O'F——, æt. 35, I saw in consultation with Dr. Savage and Dr. Gibson in July, 1907. In the previous April she had her first attack of gall-stones, during which she was jaundiced, and which lasted for about three weeks. Her present attack had lasted about a week. She was deeply jaundiced, was collapsed, had continuous pain, quick pulse, and a temperature ranging about 101°. Vomiting was present; she complained of great tenderness all over the right side of the abdomen; the abdominal muscles over the same region were quite rigid. We diagnosed perforation of the gall-bladder and had the patient removed to a nursing home, with a view to having operation immediately carried out. On opening the abdomen, bile and pus escaped freely from the peritoneal cavity. I found the viscera and the peritoneum covered with flakes of thick lymph. On further examination, I found a large opening towards the neck of the gall-bladder through which bile and calculi had freely escaped into the peritoneal cavity. Luckily, the whole area was isolated by adhesions, so that I had only localised instead of a general peritonitis to deal with. I removed 18 large calculi from this pouch of peritoneum and from the gall-bladder, and had to content myself with providing for free drainage from both. Being purely a life-saving operation, and being afraid of breaking down adhesions and thereby carrying infection to the general peritoneal cavity, I made no attempt to expose or palpate the bile ducts. The patient's recovery was slow and was not complete. After about two months she went for a trip to Portrush, and there the biliary fistula, which remained open since the operation, became closed. A few days subsequently she suffered from another attack of biliary colic. This lasted only a couple of days, and she again became comparatively well. However, she was never free from pain, she did not gain strength, she had attacks of vomiting, and a complete distaste for food. The attacks of colic recurred again and again, increasing in frequency and in intensity until they were practically continuous. She gradually also became deeply jaundiced. In January of this year I again saw her in consultation with Dr. Savage, and we were both agreed that the trouble was obstruction of the common bile duct by calculi, and that the remedy was operation. This I carried out a few days subsequently. Through the usual incision in the right rectus muscle I had considerable difficulty in getting into the abdominal cavity, as the stomach and colon were adhered to the anterior abdominal wall. The liver was well under the ribs and the gall-bladder buried in adhesions down towards the posterior abdominal wall. With great difficulty I exposed the gall-bladder and bile ducts and was enabled to palpate them. There were no calculi in the gall-bladder, but the cystic duct and common bile duct felt like a rosary of beads, from the number of calculi they contained. I incised both, removed two calculi from the cystic duct and six from the common bile duct. I stitched a drainage tube into each duct, surrounded them with strips of iodoform gauze, and suturing the abdominal wall completed the operation. The patient's recovery was rapid, complete, and I hope permanent.

It will be noticed that each of these two patients had only one attack of biliary colic previous to very grave troubles supervening. It should warn us that a patient is no more safe with a gall-stone in a gall-bladder than with a suppurating appendix in the abdomen.

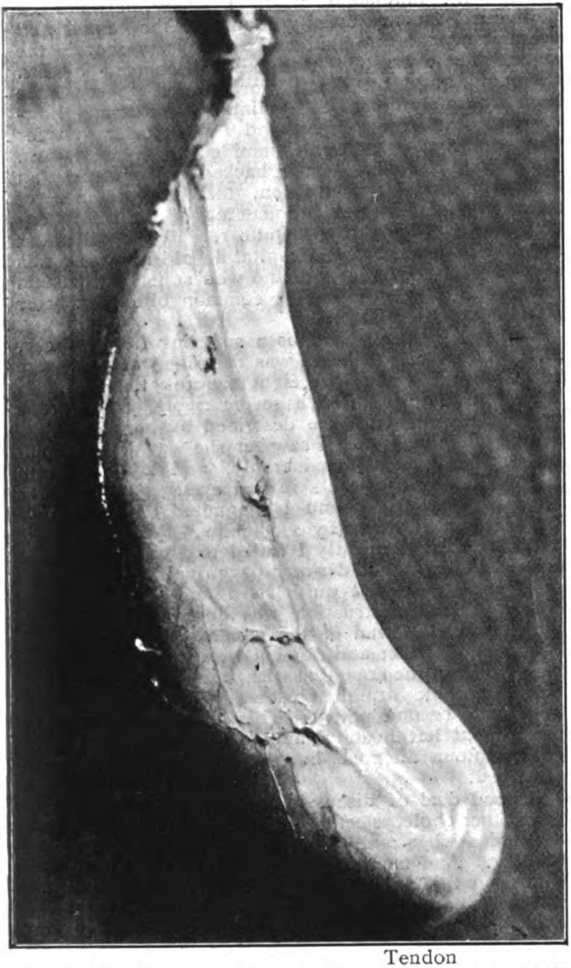
It is important for us to remember that obstruction of the common bile duct is sometimes brought about by inflammatory trouble in the head of the pancreas; and, still further, that this pancreatic inflammation may be the result of the presence of calculi in the gall-bladder or bile ducts. As one would expect, the symptoms of obstruction to the common bile duct, are pretty much the same in both conditions. But with a careful examination certain important points of difference can usually be discovered. In obstruction due to pancreatic inflammation, the gall-bladder is usually enlarged, sometimes even forming a tumour palpable through the abdominal wall. Besides, particles of undigested fat are usually found in the fæces, and peculiar crystals are said to be always present in the urine. These crystals have been discovered by Dr. Cammidge, and the details for their discovery have been accurately described by him. These details, however, are rather elaborate, and I must refer you for their description to Dr. Cammidge's original work. He claims, and his claim is backed up by no less an authority than Mayo Robson, that the presence of these crystals is pathognomonic of inflammatory changes in the pancreas. Quite recently I had under my care in Jervis Street Hospital an old lady who was sent to me by Dr. Savage, and who suffered from this pancreatic obstruction of the common bile duct. Her history was as follows:—

For two years she had been suffering from attacks, at long intervals, of what was described as gall-stone colic. But for the last eight months these attacks were associated with such severe rigors and nervous symptoms that they were described by her people as being epileptic. When I saw her she was deeply jaundiced, had wasted considerably, and suffered from intense irritation of the skin and eyes. The liver was apparently enlarged, and I diagnosed obstruction of the common bile duct by a calculus. When operating a few days subsequently I failed to find any calculus either in the gall-bladder or biliary ducts, but the head of the pancreas felt quite hard and indurated. I concluded the obstruction was due to inflammatory trouble in the head of the pancreas; I opened the common bile duct and fixed a drainage tube into it. This I did in the hope that with free drainage the pancreatic trouble would subside and the common bile duct again become patent. This hope was fulfilled, as the patient left hospital a couple of weeks ago with her symptoms all gone, but a small biliary fistula still remained.

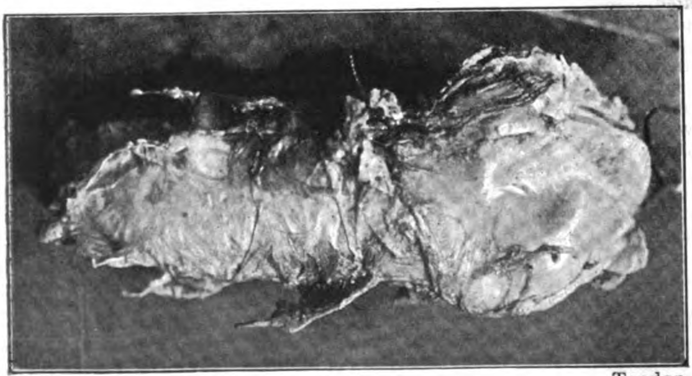
A good deal of discussion has been indulged in as to whether cholecystectomy should not be the operation of choice when gall-stones are present in the gall-bladder. And many supposed advantages are alleged to favour this procedure; but we must remember that the gall-bladder may be of great use surgically for purposes of draining the biliary ducts, or for carrying out an anastomosis with the intestine in case of permanent obstruction to the common bile duct. And in the absence of some definite condition, such as malignant disease or occlusion of the cystic duct, that calls for removal of the gall-bladder, cholecystotomy is the operation that should be done. On two occasions I have removed the gall-bladder. In both I considered that the conditions present warranted the operation. The cases are as follows:—

Mrs. O. K. was sent to me by Dr. Kelly, of Portumna. She had been ailing for about ten months, and during that time had a couple of severe attacks of abdominal pain, with vomiting. In the interval of these attacks she was comparatively well, but a tumour gradually formed in the right upper half of her abdomen. On examination, the symptoms were practically negative other than the presence of a well-marked tumour, and some wasting of the patient. She had neither a pain, jaundice nor vomiting. At first I was inclined to think the tumour was renal in origin, but an examination of the urine and of the bladder with the cystoscope gave negative results. Besides, the tumour was dull on percussion, and consequently I decided it was growing either from the liver or the gall-bladder. Through an incision through the right rectus muscle I opened the abdomen, and found the tumour to consist of a large gall-bladder extending from the costal margin down below the brim of the pelvis, and containing numerous calculi. This gall-bladder resembled in shape and size a small stomach. On examining it I found the cystic duct occluded with a calculus, and I at once determined to remove the whole thing. This I carried out without the slightest difficulty. The patient made a rapid and perfect recovery, and has remained well since.

The second case of cholecystectomy was done for a patient sent to me by Dr. Cusack, of Cashel. This was much more difficult, as the gall-bladder was adherent to the surrounding viscera. The breaking down of these taking a considerable time, and causing pretty free bleeding from the liver surface after their separation. As in the other case, the gall-bladder was filled with calculi, and one was firmly impacked in the cystic duct. She also made a rapid and complete recovery.



Gall-bladder removed from Mrs. ——. It reached below the brim of the pelvis and contained numerous calculi.



Gall-bladder with calculi removed from Mrs. K. The dense adhesions which had to be cut through before removal are well shown.

Apart from the details connected with any of the operations on the gall-bladder or biliary ducts, there are a few general principles that should always be borne in mind. A sandbag or cushion placed under the back of the patient brings the gall-bladder and biliary ducts quite near the anterior abdominal wall, and consequently renders the manipulation much more simple. The incision through the outer border of the right rectus, prolonged upwards and inwards, as described by Mayo Robson, gives the easiest access to the bile ducts. The bile ducts must be examined as a routine practice, if necessary any adhesions present being broken down for the purpose.

The area of operation must be well walled off by suitably placed pads, and the less changing there is of these pads during the operation the better.

No attempt should be made to crush a calculus *in situ*, but incisions may be freely made through any part of the bile ducts for the removal of a calculus or for drainage.

I frequently find the gloved or ungloved finger the best scoop for removing calculi from the gall-bladder.

We should remember that our operation fails to be a success unless we free the biliary ducts from calculi, and this procedure may tax to the utmost our skill, energy and perseverance to bring it to a successful conclusion.

THE DIAGNOSIS AND TREATMENT OF SYPHILITIC NEURASTHENIA.

By G. MILLAIN.

Physician to the Paris Hospitals.

The diagnosis of syphilitic neurasthenia is, as a rule, fairly easy; indeed, close scrutiny of any single symptom may enable us to come to a conclusion. The headache, for instance, is very characteristic, there is a sensation of emptiness, of weight, of compression, rather than of actual pain. Then, too, it comes on in the morning on awakening, clearing up towards evening, never interfering with sleep, and getting better as soon as the patient lies down, and it may persist for years.

The course and development of the symptoms, again, will greatly assist us in arriving at a positive diagnosis. Note, for example, the multiplicity of the painful sensations of which the patient complains during the day, or even during his quarter of an hour's conversation with his doctor. Then, too, their mobility, coming one day and disappearing the next, only to recur after longer or shorter intervals, their indefinite duration, spreading over several years, with intermissions, their presence in a subject who in other respects appears to enjoy the best of health and independently of any somatic sign, in spite of its old standing, all these are valuable elements in the diagnosis.

The characteristic features just enumerated enable us to distinguish between neurasthenic headache and that of cerebral syphilis, which is severe, nocturnal, interfering with sleep, and running its course in a few weeks or months, terminating either in recovery under mercury and iodides, or the supervention of obvious organic lesions.

There are, however, cases in which an exact diagnosis presents no little difficulty. We meet with subjects suffering from typical organic syphilitic headache, who get well in the course of a few weeks under appropriate treatment. Some time, soon after recovery, the headache returns, and once again subsides under a repetition of the treatment. This may take place several times over in the course of a year, but each succeeding attack proves less amenable to treatment, the character of the headache changes, and it is extremely difficult to make out whether we are dealing with syphilitic headache, a functional disturbance following cicatrised organic lesions, or a neurasthenic headache. Such patients must be kept under observation, and we may have to suspend our judgment for two or three months while we investigate the exact nature of the attacks, the times at which they supervene, the precipitating causes and the effects of treatment.

There are two principal forms of neurasthenia: the cerebral or cerebro-asthenic form, associated more particularly with headache, insomnia, depression of the intellectual faculties, aboulia, and various phobies; and the spinal or myelasthenic form, the principal symptoms of which are rachialgia, vertebral hyperæsthesia, thoracic or abdominal pain, weakness of the legs, and even lightning pains, impotence, etc. Both these forms of neurasthenia are met with in syphilitic subjects, and are with difficulty distinguishable, the former from general paralysis at its onset, the latter from the pre-ataxic period of locomotor ataxy.

It is almost impossible to discard the possibility of general paralysis from one's mind, in presence of these aboulic, phobic syphilitics suffering from headache and general depression, and we are often constrained to await further developments. The neurasthenia may last for years without any evidence of actual cerebral mischief, whereas general paralysis reveals its presence by mental disturbances, which assume the aspect of dementia or mania. Lumbar puncture is often of assistance in such cases, because general paralysis is accompanied by cerebro-spinal lymphocytosis.

It may happen, though rarely, that general paralysis, especially at the onset, is not associated with cerebro-spinal lymphocytosis, so that a positive conclusion can only be drawn when we find actual lymphocytosis, that is to say, the presence of lymphocytosis will lead us to decide in favour of general paralysis. Its absence only amounts to presumptive evidence in favour of a diagnosis of neurasthenia.

Tabes is also very difficult to differentiate from simple neurasthenia in its myelasthenic form. It would, however, be rather surprising if attentive clinical examination failed to reveal one or more of the pathognomonic symptoms of tabes—the abolition of one or both reflexes, Westphall, Romberg, or Argyll-Robertson's sign, ulnar anæsthesia, disturbances of micturition, etc.

Latent Graves' disease, again, is sometimes by no means easy to distinguish from neurasthenia, especially when the latter happens to be associated with disturbance of cardiac function. The headache and the mental condition may enable us to make up our minds, but there are cases in which we cannot but hesitate; in which, indeed, we may be led to infer the co-existence of the two morbid states.

Lastly, as Dutil points out, "apart from the well-defined neuroses, neurasthenia, hysteria, and the vesanic states, there is a whole series of neuropathic states, as yet unclassed, which we must be careful not to confound with neurasthenia. It is admittedly extremely difficult to establish the lines of demarcation, but it does not follow that all eccentric, debile, unbalanced subjects, neuro-arthritic and migrainous subjects who display a certain tendency to depression and complain of vague pains, ought to be classed as neurasthenics. We must, at any rate, discover in the patient, some of the fundamental symptoms which constitute the morbid type: headache, rachialgia, dyspepsia with gastro-intestinal atony, cerebral depression, a particular mental state, neuro-muscular asthenia and insomnia, all these being the symptoms described by Charcot as the true stigmata of neurasthenia.

Treatment.—The treatment of neurasthenia is a very delicate matter, and, more than any other, demands special tact and patience on the part of the practitioner. Syphilitic neurasthenia falls within the scope of this injunction. Every kind of neurasthenia entails two distinct treatments, ætiological and symptomatic, and this remark applies with equal force to syphilitic neurasthenia.

The ætiological treatment of syphilitic neurasthenia must be twofold—the treatment of the determining cause of the neurasthenic state, and the treatment of the syphilis proper. With respect to the former, we must ascertain to the best of our ability what is the most salient feature of the patient's preoccupations—is it his pathological future, the possibility of getting married, the risks of contagion, and so on, and we must reassure him on this point as far as is humanly possible. We must not be satisfied by replying to his various questions in the negative, for they are usually suggested by things that he has read; so we must try and convince him that what he reads in books can only apply to a very small proportion of such cases—in fact, only to persons who have not been properly treated, or who, during treatment, led an irregular life. He must be persuaded of the beneficent effects of treatment, and induced to base his hopes thereupon.

In short, he must be reassured by showing him the remedy side by side with the evil. Above all, we must not display inattention when he is telling us of his woes, we must not interrupt him abruptly under pretext that he is too diffuse; on the contrary, we must let him see that we are devoting our whole attention to his narrative, and must reply with patience and tact to his questions. Avoid, above all things, treating his complaints as imaginary, for in this case he would logically conclude that you cannot possibly cure him, since you do not believe in the reality of his ills. If the physician, by a sympathetic, tactful attitude, can only succeed in gaining the confidence of his patient, the battle will already be half won.

At the same time we must immediately commence the anti-syphilitic treatment. In this secondary neurasthenia the effect of the treatment will be immediate and striking. The asthenic symptoms will follow the same lines as the cutaneous eruptions. The intensive treatment is the more indicated seeing that at this stage such patients bear mercury remarkably well, for all the world as if there were some relationship between the quantity of mercury that can be injected and the outward and visible manifestations. Under the direct influence of the treatment the asthenia will disappear, and the mental state will improve *pari passu* in view of the obvious influence of the treatment on the visible manifestations.

The treatment is much easier at the tertiary period. We all know the depressing influence and the general fatigue produced by the iodides and mercury, especially when the latter is given hypodermically: fugitive it is true, but none the less real. The neurasthenic subject often feels much weaker under the influence of the mercurial treatment, and it is difficult to get him to understand how his recovery can be brought about by a method which begins by intensifying his previous symptoms. It is therefore necessary to warn him beforehand on this point, while, on the other hand, the practitioner does his best to devise a treatment that entails a minimum of discomfort, and can be continued for a sufficient length of time. If grey oil be used in view of a protracted treatment, only a small dose should be given—say 3 centigrammes at each injection, to be repeated twice a week instead of the usual plan of injecting 7 cg. once a week. If pills are prescribed, preference should be given to sublimate pills containing a sixth of a grain in each, one with meals twice a day. Benzoate of mercury is given in doses of 2 cg. every other day, never exceeding this quantity, which is in some instances too strong.

Lastly, it is undesirable to continue the same treatment indefinitely. As soon as any untoward symptom makes its appearance, we must change the drug. Instead of grey oil, we may employ the benzoate of mercury; instead of injections we may give pills; pills may give place to inunctions in order that the mercurial course may not be interrupted. Or, instead of the mercurial course, we may order arsenic, which has the double advantage of prolonging the antisyphilitic action of the treatment, and of acting as a general tonic. Arseniate of soda may be prescribed in doses of a sixth of a grain a day, either by the mouth, or, still better, by hypodermic injection. This is persevered with for a month, whereupon iodide may be given in whatever quantity the patient can tolerate—say, from 10 to 40 grains daily. After four months of this alternative antisyphilitic treatment, it may be suspended for a month, to be followed by two more months of mercurial treatment, one of arsenic and one of iodide.

Symptomatic Treatment.—The general health of the neurasthenic patient has everything to gain by a period of rest in the country or at an altitude. The seaside, being more stimulating, does not appear to suit them as well. Faradic electricity and massage are often valuable adjuvants.

Weir-Mitchell's plan of absolute isolation may be found useful in grave cases, and when the patient's surroundings are unfavourable, as, for instance, when his friends and relatives, under pretext of testifying to their interest, are everlastingly asking him about his health.

The headache, the pain, and the digestive disturbances, must be treated separately. It must be conceded that they often resist medicinal treatment, and disappear little by little, just as they came without any obvious explanation of their behaviour.

Pyramidon and injections of isotonic sea-water, however, often exert a favourable influence. In neurasthenic subjects generally it is important to keep the bowels empty, and we must see to this by ordering appropriate aperients, enemata, and abdominal massage. Many of these patients are only "themselves" just after going to stool.

THE TREATMENT BY DIET OF BRONCHIAL ASTHMA. (a)

By A. C. F. RABAGLIATI, M.D.Ed., F.R.C.S.,

Consulting Surgeon to the Bradford Children's Hospital; Hon. Gynæcologist to the Bradford Infirmary.

This case is that of a young gentleman, æt. 25, who came to me along with his mother on October 11th, 1907. They told me that from the age of two years he had suffered from recurring attacks of asthma, that is, that he would suffer, say, for ten days at a time or for fourteen days or so from severe cough, during which time, although confined to bed, he was unable to lie down, because of the distress of breathing, and that there were loud whistling sounds audible in the breathing, with feverishness, quick pulse, high temperature, loss of appetite, etc. After recovery he would be able to be about again for a week or two. Even when well, however, he never could lie down with fewer than four pillows to support his head, as lowering of the head brought on difficulty of breathing, and might wake him out of sleep and compel him to sit up. Further, in the morning, even when well, or apparently well, he always coughed to get rid of some phlegm. During the attacks the marked tendency to suffer from an exacerbation of cough and breathlessness, or a sudden onset of distress of breathing in the small hours of the morning—1, 3, or 5 a.m.—was so noticeable as to have forced itself on the attention of the patient and of all the members of his family. I suppose it is this feature which in popular language, as well as in medical terminology, determines the naming of the disease ἄσθμα. When symptoms of bronchial catarrh, without pneumonia, are present, *i.e.*, cough expectoration and feverishness, the affection is called bronchitis: when distress of breathing is super-added to these, and particularly when the distress prevents the patient from being able to lie down and compels him to adopt the sitting position, the affection is called asthma. Of course, there are numerous intermediate gradations and conditions of bronchial catarrh in various patients, the symptoms of bronchial catarrh prevailing in some and those of distress and orthopnœa in others. "Nervous asthma," I may remark, a condition which I used to see in my earlier days of practice, or which I used to think I saw, I never see now; and have not for many years. I believe that bronchial asthma is always catarrhal and inflammatory. And treatment suggested by this belief has resulted in this—that whereas I formerly believed asthma to be one of the least tractable of conditions, obscure in its nature, erratic in its manifestations, uncertain in its course, and little amenable to treatment, I now believe it to be one of the most tractable of diseases and one as to which it is most easy to promise cure of patients who will follow the advice given to them. The cases one sees have usually lasted for a long time, that is, the attacks have usually recurred from time to time, as in this case, over a long series of years; and treatment, to be effective, must be continued for a considerable length of time if relief is to be effected, because, of course, Nature cures each attack herself by compelling the patient to take his bed, stopping the appetite, furring the tongue, raising the temperature, and quickening the pulse, as she does in acute and in recurring diseases generally.

Probably the most fundamental law in medical practice is that illness is long-lasting or frequently recurring, in proportion to the length of time during which the inducing causes have been in operation. I may at once say—for it is the essence of this communication—that as it is the discovery that wrong feeding is far the most important factor in the causation of asthma, as it is this discovery which has given one confidence in promising cure in a large number of cases, it follows that after recovery a patient must on no account return to his old way of living—or he will be ill again. It must be so. If the action of certain causes makes a person ill, and if the removal from the sphere of those causes enables him to recover, obviously re-subjection to the action of those causes must make him ill again. And conversely, if he wishes to escape new attacks he must continue to live in a new way—and not to put too fine a point upon it—for it is just here that our difficulties with patients are greatest—he must in the future eat less and less often.

To proceed with the history of this case: the mother told me that they had suffered so much in having to attend to the child, boy and man during practically the whole of his life, and were so tired of the recurrence of the attacks, one being no sooner recovered from, as a rule, than he had entered on another—they were so sick of these experiences that they were prepared to do anything I advised. She incidentally coloured the narrative by suggesting that, as the boy had not been well since he had been vaccinated, vaccination was the cause of his illness. There was, however no proof whatever of this allegation; and, in fact, it was not quite compatible with the other statement that the child had suffered from asthma from the age of two years; as vaccination, performed under the age of three months, might have been expected to show its hurtful influences sooner than 21 months after the operation if it had any hurtful effect at all. Finding my patient in the thus hopeful mental state of being willing to do anything in order to get well, as he and his family were so thoroughly tired of the futility of all previous treatment, a fortnight's illness having been followed for many years by two or three weeks' recovery, or partial recovery, and the partial recovery by another attack, and so on indefinitely; I said that unless I found consumption or some other incurable condition present, I had no doubt about the curability of the asthma and the chances of preventing subsequent attacks. On examining the patient I found a markedly emphysematous chest, barrel-shaped, with prolonged expiration and whistling sibilus more or less all over it. He was not very ill at that time, being able to be about. In fact, the object of his visit was to get advice as to the preventibility of future attacks, which, from experience, he well knew he might expect. There was no attack on then. He incidentally mentioned that he had lost eight relations by death in 1907. But this unfortunate experience, while it no doubt rendered his family more anxious on his account, had no distinct bearing on his illness. I showed him that, besides the emphysema and the recurring colds of which he knew, as his attention had frequently been directed to them, he was suffering from periostitis of the sternum, which was very tender on pressure just above the xyphoid cartilage, that he had arthritis at each sterno-costal cartilage, especially the 4th, 5th, and 6th left, and that many of the muscle sheaths, as, for instance, the sterno-mastoids, trapezii, rhomboids, teretes majores, etc., as well as those of the lower limbs were tender on pressure, showing the general initis or rheumatic congestion from which he suffered, and which appeared to me to be at the bottom of his asthma. But mal-assimilation was at the bottom of the general initis; and it was necessary, therefore, to deal with the mal-assimilation if any influence was to be had on the illness. Meantime, in order to treat the catarrh of the mucous membrane of the lungs, I advised the use of a wet flannel compress for an hour morning and evening. This compress to be made of flannel about 18 in. wide and a yard and a quarter long, put wet round the chest and covered with two or three dry blankets; a cool application to be placed also on the forehead to prevent headache. He was to take a demulcent expectorant two or three times a day, and some sedative in a wineglass full of hot water at night, if required.

(a) Read before the Bradford Medico-Chirurgical Society, June 16th, 1908.

About food: he was to have a cup of hot tea, weak, in the morning at breakfast-time with nothing to eat; and to dine early for the present (by and bye I hoped to make some more satisfactory arrangement as to this). Dinner might be as early as 11.30 or 12, with a plain tea, without jam, at 7 p.m., and no other food. On this plan he improved from the first. He came to me on October 17th, 24th, and 31st. He did not lose weight to any appreciable extent under the treatment, remaining about 7 st. 7 lb. (height 5 ft. 3 in.). He had weighed 7 st. 13 lb. two months before I saw him. On the night of October 30-31st he had been awoke at 3 a.m. with dyspnœa. There were some sibilant *râles* in the chest. On November 7th he was much better. I had, however, warned him that the progress which I confidently expected, would be (like the onset of his illness) intermittent, and that he could not expect to recover straight away. On November 27th he was sleeping right through the night and was much improved. Still we were not greatly surprised that on December 18th he had "a cold" and lost 3 lb. in weight down to 7 st. 5 lb. After this I advised him to have a cup of tea for breakfast simply, dinner about 11 a.m., as under the new *régime* he still found it hard to wait longer (and also because I did not wish to put too much strain on him yet) a cup of tea at 5 p.m., and about 7 a glass of Allen and Hanbury's Food or Horlick's Malted Milk or Maltine with Milk. On this he did very well for some time.

After the beginning of the year I advised him to wait for his first meal till he could join the family dinner party at 1.30; to have a cup of tea alone in the morning; and about 7 to have Horlick's Malted Milk or Benger, or Allen and Hanbury without bread. On February 5th he had gained weight on this practically monositious *régime* to 7 st. 9 lb. I advised him to abstain from Yorkshire pudding and pastry, but otherwise to take at the family dinner whatever was set before him. On March 12th he had gained another pound in weight, eating once a day (this is, however, not an uncommon experience in practice, I have many observations of patients who gain body weight by eating less—the explanation, I suppose, being that if they eat less, they assimilate better what they take; on that day one could hear some fine dry sibilant *râles* over the back of both lungs. But he was sleeping right through the night with one pillow and a bolster, not the four pillows of former times, was going out in all weathers without any fear of catching cold, and was getting up early in the mornings to look after his fowls in the country place where he lived. He has continued this *régime* up to the present, and remains well. The emphysema is not gone; probably never will quite go; but it does not incommode him. Under the breathing exercises I recommended for him in the mornings (which, although I advised them I omitted to mention), as also under the general methodised exercises I advised him to have in the act of dressing, as well as the free expiration recommended, no doubt the emphysema will become less and less. Whether it will ever be quite got rid of is doubtful.

I do not know if my medical colleagues have noticed what I call the delusion of the asthmatic? He feels as if he could not get his breath; while, in point of fact, he can't get rid of it. The asthmatic, if you watch him in the paroxysm, takes a succession of forced inspirations at very short intervals between one another; and he hardly expires at all. You can frequently mitigate an asthmatic paroxysm by persuading the patient to expire freely and long. Often and often have I been able to shorten an attack by this means. "Breathe out, exhale, expire," you say to the patient; and in a little while he begins to obtain relief. And obviously the fact that emphysema follows asthma, or makes part and parcel of the asthmatic condition, is a fact corroborative of this view, for otherwise if the patient could not get air, atrophy of the lungs would be the dominant pathological condition instead of over-distension.

I have no doubt that this young man, who has suffered so much and for so long a time, and so recurrently, that his parents have taught him no trade and no profession, can remain well so long as he continues to follow his present mode of living. Equally little doubt have I that if he returns to the conventional 3, 4, or 5 daily meals, he will have a recurrence of his illnesses. He may make this differential experiment if he likes. I do not advise him to do so. What is the use, one is driven to ask—what is the use of advising a patient suffering in this way, to avoid cold, to avoid draughts, to avoid fatigue, etc., etc.? Is it not much better to advise him that if he is to live at all (and he cannot help himself as to this, for he is alive without his consent being asked) he had better adapt his way of living to the country and climate he is in than fly to other climes, where if he gets rid of one set of ailments he will almost certainly suffer from some others? In the matter of climate it seems to me it is far rather how we live than where. I might have paralleled this case by many others treated on similar lines, and treated equally successfully, but I leave the natural and logical inferences to your own minds. I am not by any means the first to have drawn attention to the influences of wrong dieting in causing dyspnœa, nor even, perhaps, to have shown the immensely beneficial effects to the sufferer from asthma, of advising him to eat nothing after about the middle of the day (12 to 2 p.m.). But I seem to have rediscovered the principle that the great majority of asthmatics will recover in a few weeks or months, and not fall ill again if they follow this simple rule. I think it is an excess of carbonaceous stuffs that are efficient in causing asthma, and therefore I am careful to advise an alteration of the diet in this direction. Still, an excess of *any* sort of food beyond the bodily requirements is hurtful in some direction—if not in causing asthma, then in some other way. So that very good advice is that the patient should not eat after mid-day, and then in moderation. I remember being told by a distinguished physician of the vagaries of asthma, and how you never could predict what plan would suit, and what other would not suit the asthmatic patient. I listened with open mouth as he told me of a mother and son, very much attached to one another, and both asthmatic; but the place which suited the mother did not suit the son, and so they could not live together—which was a great distress to them—but could meet only occasionally and at very long intervals, at some neutral place for some short time and then part again. I have often wondered since whether, by making simple changes in their dietary, these two unwillingly separated relatives might not possibly have been able to re-unite. It would be still more awkward if, instead of being mother and son, the two had been man and wife! ! ! I have thought your readers might feel interested in the details of this case. I have not dealt with the pathology, except incidentally, and I can well imagine that some here might be disposed to cavil at my definition of disease, viz., that it is generally the process by which Nature eliminates unnecessary material from the body, which unnecessary material mostly finds its way in through the digestion. But I do not enter on the discussion of this point. There are, however, as Professor Stewart says, few diseases which are not in some sense alimentary.

OUT-PATIENT'S ROOM.

METROPOLITAN HOSPITAL.

Gout.

By LEONARD WILLIAMS, M.D., M.R.C.P.

This man, æt. 44, and who is a "handy-man," comes to us with an interesting story, which, in the light of his symptoms and physical signs, becomes extremely instructive. He has been suffering from tenderness in his hands, feet, and knees for 23 weeks, of which 8 weeks have been spent in bed. The diagnosis at the institution where he has been treated was "rheumatic fever," and he tells us that he suffered a similar attack, also labelled rheumatic fever, three years ago. Fourteen years ago he had an illness of the same nature. He is quite certain of the fact that in none of these attacks did his joints swell. They were very painful and rather red, but there was no swelling. He further tells us that, in the last attack, at any rate, he never had a high temperature. This he knew, not only because he kept his eye upon the chart which was hanging above his bed, but also because he did not feel ill in himself. He had no sweats, and the pains did not fly from one joint to another. Now, in the light of this story (and I think you will admit that the patient is an exceptionally good witness), we need have no hesitation whatever in saying that, certainly so far as his last attack was concerned, and probably so far as the two previous attacks were concerned, this man has not had the disease which is known as acute rheumatism or rheumatic fever. He has had an arthritis—of that there can be no doubt. If there were any, it would at once be dispelled by an examination of his hands, which have the appearance so characteristic of a sub-acute or chronic arthritis from whatever cause arising. That is a point to which I would direct your very special attention. If the joints of the hands become sub-acutely or chronically inflamed, there is no means by which you can be sure of the cause of the inflammation if you confine your examination to the joints themselves. Arthritis is like pleuritis or conjunctivitis, or any other inflammation which may be produced by various causes. To discover the meaning of an arthritis, it is necessary to examine the patient rather than his joints; to restrict your view to the latter is to court misfortune. If we were asked to describe this man's general appearance, we should say that it was that of a person of robust physique; over-nourished rather than the reverse, but without evidences of any excess. He has been a teetotaller for thirty-five years, but remembers that both his parents, especially his mother, "were very fond of their glass of ale." He has always been a hearty eater. You notice that he is prematurely bald, and, if you examine his mouth, you will see that the gums have receded considerably, and that he has what dentists call erosion cavities between the gums and the dentine. When you look at his hands you will observe that his nails have that longitudinal striation which is described as "reedy," that he has the enlarged metacarpo phalangeal joint of the index on each side, the over-extension of the proximal and the flexion of the distal phalangeal joint in several of the fingers, which tells of a chronic or sub-acute arthritis. On these findings alone I have no hesitation in saying that this man is gouty, though I confess that if you press me for a definition of this term I should find it very difficult to supply you with one which could be considered as altogether satisfactory. The truth is we do not to-day know much more about gout than they did in Sydenham's time; certainly we know very little more about its pathology than was then known. Theories there have been, and still are, some of which are plausible, but none of which contribute anything to a real understanding of the disease. Of one of them, the uric acid theory, it is indeed possible to assert that it has done more to darken counsel, to obscure the real issue, and to retard progress than anything else. Gout is no more due to uric acid than consumption is due to "chill." And if we are not in a position to explain gout, we are still less equipped for dogmatising about goutiness. Nevertheless, goutiness is a condition which we must learn to recognise clinically, and the earlier we can recognise it the more likely are we to be able to guide the patient into those paths of physiological righteousness upon which his salvation depends; for the treatment of goutiness is far more a question of general hygiene than it is one of drugs. The stigmata of the gouty diathesis are many. Some of them we have already seen this man to possess; from others he is free. One of the latter, namely, cutaneous eruption, is a very common finding; it is, indeed, probably the manifestation which most often drives the patient to the doctor. Another common manifestation which is present in this case is varicose veins, which more often than not take the form of hæmorrhoids. In such cases gastro-intestinal troubles are almost invariably complained of, and they generally take the form of dyspepsia of the acid, sthenic type, which is relieved by bismuth and soda, and constipation, which requires the occasional administration of mercury for its complete relief. The state of the cardio-vascular system in the gouty is one of very considerable interest and no little complexity. The French say that gout is to the arteries what rheumatism is to the heart, meaning that gout is as liable to cause arterial degeneration as true rheumatism is prone to produce endocarditis. The method of production of this arterial degeneration is believed by many to consist in the production of hypertonus by the gouty toxins, giving rise to high blood pressure and consequent fibrosis. This may be the mechanism in some of the cases. I will even go so far as to say that I am convinced that it is the mechanism in many of them, but I am quite as certain that in a certain proportion the mechanism is entirely different. This man is a case in point. His blood pressure is not only not high; it is, for his age, distinctly on the low side. We have taken it twice, and on neither occasion did it rise above 120 mm. Hg., which, though normal for a man of 24 years of age, is certainly below the normal for a man of 44. When you examine this patient's heart you will find the apex-beat, as it is improperly called (the *élite* now call it the "impulse point") in the nipple line—that is, somewhat to the left of its proper place. There is no enlargement in any other direction. With the stethoscope you will hear a faint systolic murmur in the mitral area which is not conducted, and at the aortic base a loud systolic murmur which is conducted into the vessels of the neck. Now what is the significance of this basal murmur? If you believed the text-books you would have to conclude that it meant stenosis of the aortic orifice; they give you no alternative; they tell you that a systolic murmur at the aortic base means obstruction at the aortic valve, as inevitably as two and two make four. But text-books are devoid of imagination, and do not realise that the calcareous degeneration of the first part of the aortic arch which we so often see on the post-mortem table will produce a rough systolic murmur in the aortic area even more effectually than a narrowing of the aortic ring will produce it. The point of interest here is to discover what has caused this calcareous degeneration. We know that syphilis is a very potent cause, but, without going into details, I may say that such a cause has been almost certainly absent in this case. High blood pressure is, as I have already said, another very common cause, but the manometer tells us that this patient's blood pressure is low. One may of course reasonably ask if the pressure has always been low, or whether it is not possible that it has been high, that it remained high for a sufficiently long time to bring about the chronic aortitis of which we now find the evidence, and has since fallen to the point which the instrument now registers. That, no doubt, is a possibility, and it is a possibility which would seem to be supported by the slight outward displacement of the impulse point, but I can hardly bring myself to regard it as a probability. A fair proportion of people who are definitely gouty have low blood pressures all along, in the same way as many of them have a subnormal temperature all along, and I believe that persistently low blood pressure may bring about an aortitis almost as effectually as a persistently high blood pressure. This is, however, a question which is rather too intricate for present discussion, so I pass to the more congenial atmosphere of treatment. I have already said that the treatment of these cases is largely one of general hygiene; but it is one of general hygiene as applied to the individual. There is no use telling a man who works hard with his muscles in the ordinary way that he must take exercise. It is quite evident that such a man has become gouty, as this man has, in spite of the exercise. We must therefore look to some other factor. In all probability that factor will be found somewhere in connection with his diet. There are people who "throw back," so to speak, to their Simian ancestors, and are consequently unable adequately to metabolise meat foods, in the same way that there are pepole who "throw back" to their carnivorous ancestors, and are unable adequately to metabolise carbo-hydrate foods. In either case if the patient adopts the ordinary plan of eating a mixed diet, some form of goutiness will result. So far as drugs are concerned, guaiacum and iodide of potassium are the most generally useful, but there can be no doubt that salicylate of soda, especially in the form of aspirin, will occasionally succeed when these others fail. Where the goutiness takes the form of arthritis nothing, in my experience, does so much good as radiant heat baths. Where the blood pressure is high, as in some of these cases it is, I find that ipecacuanha in small doses, not sufficient to nauseate, does a great deal of good; but where the blood pressure is low, as it is in this man's case, even if I am moved to give ipecacuanha for the purpose of stimulating the liver, I always protect its action by the addition of a certain proportion of nux vomica. Were this patient a rich man instead of a poor one, I should have no doubt whatever as to how to treat him. I should send him to Vichy, where he would be subjected not only to the sodium bicarbonate waters, but also to electricity, massage, and a scheme of diet, based upon a careful investigation of his digestive capabilities.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Cases of Appendicitis.

(*Concluded from p. 645.*)

Acute Appendicitis Simulating Acute Cholecystitis.—Mr. Edred Corner operated on a married woman, æt. 45, who had been ill a week with pain below her right hypochondrium, accompanied by pyrexia, sickness, inactivity of the bowels, and some jaundice. On examination, the skin of the abdomen was tinged yellow, and by the right costal margin was a tender mass, dull on percussion. Thus it may be said shortly, Mr. Corner pointed out, that the case presented all the signs and symptoms of acute cholecystitis. The mass was too far out, and there were not the concomitant signs or symptoms for it to be connected with the stomach, pylorus, or duodenum. But there was the appendix to take into account; it was a clinical factor which must always be reckoned with when the disease was on the right side of the abdomen or in the pelvis. Not infrequently it entered also into the diagnosis of troubles on the left side of the abdomen. In children the appendix was often up under the liver, which was its natural and normal situation in the fœtus. On occasions it remained in this subhepatic position throughout adult life. But the usual condition was that the free end remained more or less in the subhepatic region, the appendix being pulled out longer and longer as the cæcum descends to the right iliac fossa. As suppuration generally affects the distal end of the appendix, the abscess in these cases forms in the subhepatic region, and presents below the costal margin of the right ribs. The abscess was opened from the front, the fibres of the rectus muscle behind being separated and held apart by retractors. Yellow offensive pus alone was evacuated as from an appendix abscess. There was no bile present, but a fæcal concretion was found which proved that the appendix had been perforated. Mr. Corner pointed out that these cases in which the appendix abscess was situated high are very liable to be followed or accompanied by a subphrenic abscess, the pus being between the diaphragm and the liver. It would be therefore necessary for a very careful outlook to be kept on the lower part of the right lung behind, because it is in this situation where the physical signs are to be found. These are those of fluid; dulness, loss of breath sounds, loss of vocal fremitus and vocal resonance, etc. These signs must be particularly looked for if the temperature remained up or becomes irregular.

In the case of this patient the convalescence was slow, but interrupted by no spread of the infection.

Acute Appendicitis.—The same surgeon operated on a girl, æt. 25, who had been in a doctor's household. Recently she had come from the country to stay in London, the change in her life producing great difficulty with her bowels, a trouble she had never experienced before. There was, Mr. Corner remarked, a very great connection between inflammation of the appendix and constipation. In consequence, after being in town for some time, she woke up one night with acute abdominal pain and vomiting. Her temperature was 101°, and the pulse 110 in the morning. As a clinical feature of great importance he thought it should be noted that the attack of pain commenced in the night, waking her up. She had another bad night, and when Mr. Corner saw her the temperature was 102.4°, and the pulse 120. On examination, the abdomen was soft in the upper part; tender and not moving well in the lower. A most important point in the examination of acute abdominal cases, he considered, was a rectal examination which should *never* be omitted. It was of special importance when the signs found on abdominal examination were not decisive, such as in this case. When the abdominal examination reveals the disease and decided the treatment, a rectal examination was not nearly so helpful. In the case of this girl a hard mass was felt behind the uterus. It was tender, and its examination was painful, but it was capable of being moved which peritonitic tumours in their acute inflammatory stage are not generally. Operation was undertaken at once, the abdomen being opened by an incision through the right rectus. The uterus, Fallopian tubes, and ovaries were normal. The tender swelling felt in Douglas' pouch turned out to be a large fæcal mass in the sigmoid colon prolapsed there. There was no sign of pus, and the intestines were only slightly ingested. The appendix was slightly swollen, but its external appearance showed little. It was removed. An incision was made through the upper part of the left rectus in order to exclude the possibility of any perforation of the stomach or duodenum. Nothing was found on the anterior surface of the stomach or duodenum. The omentum was then brought out of the abdomen with the transverse colon, until it was possible to incise the transverse mesocolon and examine the posterior surface of the stomach, no perforation was found. The gall-bladder and pancreas were healthy. It was important, Mr. Corner pointed out, to examine the upper part of the abdomen for two reasons. First, perforations of hollow viscera in the *upper* part of the abdomen are often followed by clinical signs found only in the *lower* part of the abdomen. Secondly, no *certain* cause of the patient's trouble had as yet been found. Moreover, she had suffered from indigestion since being in London. Both abdominal wounds were closed in the usual manner. The appendix, which had been removed, was then slit up and examined, the cause of the illness being then found. The mucous membrane was swollen, thick, and infected. The lumen was filled with fæcal matter and blood. There was acute inflammation which had hardly extended from inside the appendix before that organ had been removed. The case might be called acute endo-appendicitis. A final clinical lesson, Mr. Corner considered, must be pointed from this case. Whenever operating on a case, which has presented signs and symptoms of acute abdominal disease, always remove the appendix, even if it is not obviously diseased, if no clear cause of the illness has been found, such as the perforation of a gastric ulcer. It is a good rule to remove the appendix whenever the abdomen is opened, provided that it can be done without prejudicing the patient's recovery.

The after history of this case is of interest or, as Mr. Corner said, "the proof of the pudding was found in the eating." Immediately after the operation the temperature rose to 103°, after which it fell to normal, and remained so. The wounds healed by first intention, and the patient left the hospital on the sixteenth day.

TRANSACTIONS OF SOCIETIES.

THE RESEARCH DEFENCE SOCIETY.

The inaugural meeting, which was a large and influential gathering, of the Research Defence Society, was held in London on Friday last, in the rooms of the Royal Society of Medicine, Lord Cromer, President of the Society, in the chair. After the committee's report had been read, announcing that the membership of the Society amounted to 1,290, including 123 ladies, and that the Society had received £474 7s. 10d., and now had a balance of £317 0s. 2d., while £100 had also been promised by the Physiological Society, Lord Cromer delivered an address, in which he remarked that in asking him to accept the honourable position of President, and in inviting so many laymen to become members, the founders of the Society had, he said, wished to show that men of science had the support of those who could lay no claim to special scientific knowledge, and that they had the support of those who had taken an active part in preventing cruelty to animals. In this respect he could claim some qualification as having for years been President of the Society for the Prevention of Cruelty to Animals, which conducted a long and fairly successful campaign in Egypt. Lord Cromer further explained that there is nothing inconsistent between an absolute detestation of wanton cruelty to animals and approval of experiments on living creatures, having for their object the relief of suffering to both human beings and dumb animals. He would go further by saying that the one attitude is the necessary consequence and corollary of the other, and that if the necessity of the experiments may, as he held, be justified by any good and sufficient reasons, their execution should be, so far as possible, watched and controlled by a body of men who would shrink with horror from anything indicating indifference or callousness to the wanton infliction of pain. If he thought that the charge of indifference or callousness could be justified, the case would be very different, and the Research Defence Society would then have to look out for another President. He then asked: What are the main grounds on which vivisection can be defended? They are twofold. In the first place, it can be shown that experiments on living animals have already produced invaluable results, and may produce results still more invaluable. In the second place, it has been shown that the experiments are conducted in such a manner as to minimise, if not altogether to obviate, the infliction of pain, both of which propositions can be proved up to the hilt. Speaking of the methods of experiment, he contended that cases of harrowing and revolting details brought forward by anti-vivisectionists very frequently turned out to be either greatly exaggerated or, he might say, almost wholly imaginary. Many of the cases constantly presented to the public had occurred in a somewhat remote past, but they had not to deal with the history of vivisection, but with the operation of the system since the Act of 1876 was passed, and he ventured to consider that the working of this Act was satisfactory. After referring to the figures for vivisections in 1907, and paying a high tribute to Professor Starling's humanity in the conduct of experiments, Lord Cromer concluded by saying that, broadly speaking, the small amount of pain and suffering caused by experiments on living animals was a price which might justifiably be paid, in view of the enormous amount of pain and suffering prevented or relieved. . . . He therefore esteemed it a privilege to be the President of this Society, and to be thus associated with a number of very distinguished and humane men, who, in the interests of science, and in their persistent endeavours to relieve the sufferings of humanity, had exposed themselves to a great deal of very unjust obloquy.

Sir **Thomas Barlow**, in proposing the first resolution, which stated that the object of the Society was to publish the facts relating to experimental research and the benefits that had been derived from it, expressed his pleasure, as a member of the "rank and file of the practising medical profession," in being able to show their absolute sympathy with those who devoted their lives to research, and their appreciation for the invaluable help which they derived from their expert brethren. The Society did not exist for the encouragement of vivisection, but for the purpose of stating the facts to the public. The history of medicine as a healing art contained much that was humbling. Advance had in many cases been due to "happy flukes," and medicine till recently had been largely empirical, and was even now overladen with useless and even dangerous empiricisms, it was only by the scientific study of the natural history of man and of the natural history of disease that those encumbrances could be removed. One of the greatest achievements of the Right Hon. Joseph Chamberlain at the Colonial Office had been the very successful efforts he made to cope with tropical diseases, and not the least of the benefits which would follow from the work of the Society was the encouragement which it would give to workers in tropical disease through the realisation that their services were being appreciated.

Lord **Robert Cecil**, in support, said that if the infliction of pain was unjustifiable, nearly all forms of sport, the riding and driving of horses, the beating of disobedient dogs, and the imprisonment of animals at the "Zoo" were condemnable, whereas the infliction of pain on the lower animals could have no higher justification than experimental research. Animals were not on the same plane, and if the treating of animals with kindness involved the treating of our fellows with unkindness, those who did so would be guilty of a grave dereliction from morality.

Mr. **Walter Long**, in moving that it should be among the objects of the Society to establish branch societies, and to take such steps as the committee should from time to time think desirable, said that he had worked in two Government departments which had dealt with similar work to that which this Society proposed to undertake, and that he regretted nothing that he had been able to do in furthering their work which resulted in the avoidance of pain, the prolongation of life, and the prevention of disease.

Dr. **Martin**, the Director of the Lister Institute, said that the public did not realise the progress that was being made in the study of cancer, nor did they know that one of every 11 men or 8 women who reached the age of 35 was destined to die of cancer.

In proposing a vote of thanks to Lord Cromer, Mr. **Butlin** gave a number of illustrations to show that it was untrue that the men who were engaged in experimental research grew callous as a result of the experiments they performed.

Mr. **Sydney Holland** said that though they were not all researchers, they were all searchers after truth. He characterised Lord Cromer as a man who was typical of everything upright, truthful, and honourable.

In a brief reply, Lord **Cromer** paid a high tribute to the ability with which Mr. Stephen Paget, Honorary Secretary, had organised the Society.

CENTRAL MIDWIVES BOARD.

Meeting held Thursday, June 16th, 1908.

The President, Dr. **Champneys**, in the Chair.

There were also present Mr. Ward Cousins, F.R.C.S., Dr. Stanley Atkinson, Mrs. Latter, Miss Paget, Miss Wilson, and Mr. Parker Young.

PENAL CASES.

The proceedings were short. In the report of the Penal Cases Committee the only item which called for comment was the case of Sarah Ann Lambert, who had been convicted under the Notification of Births Act. It was agreed that inquiries be made:—(1) As to who were present at the birth on February 15th in respect of which S. A. Lambert was convicted of failing to notify, as it was desirable to find out why the midwife was responsible. (2) As to whether the L.S.A. find a *primâ facie* case within the meaning of Section 8 (2) of the Midwives Act, 1902.

PROBATIONERS.

The Standing Committee reported on a letter from Dr. Gibson, Master of the Coombe Hospital, Dublin, inquiring whether two probationers working together, and helping each other to conduct the delivery, can each obtain credit for a conduction. The Board passed a resolution that Dr. Gibson be informed that it would not tolerate the slightest relaxation of its rules relating to attendance on cases. The **Chairman** remarked on the shortness of training and small number of deliveries necessary for entering as a candidate for examination, and declared that it would be a most dangerous thing to lessen these qualifications in any way. Another letter bearing on the same subject was read from a midwife, training pupils, who inquired if, in the case of a pupil arriving at the patient's house too late to make examinations previous to delivery, but delivering the patient, it might count as a conduction. The **Chairman** called attention to Rule C. 1 (1), and it was agreed that the same answer be given to the midwife as to the Coombe Hospital. In reply to a letter from the Secretary of the Q.V.I.I.N. as to providing facilities for the written examination in Ireland of candidates for the C.M.B. certificate, it was decided that the Board could not accede to the request.

H. W. Husbands, M.R.C.S., L.R.C.P., was approved as a teacher, subject to the furnishing of a syllabus of lectures.

MEDICAL FEES.

The statement to be submitted to the Privy Council as to the payment of fees of medical practitioners summoned to assist midwives in emergencies was laid on the table, and, after some amendment, was approved, a resolution being passed that the deputation to the Privy Council, to be arranged for an early date in July, shall consist of *all* the members of the Board.

CANCER OF THE WOMB.

At the conclusion of the meeting the leaflet on the subject of cancer of the womb drawn up by the Chairman at the request of the Board was produced. It will be sent to all local supervising and sanitary authorities, and to all training schools for midwives throughout the country, and a copy can be obtained on application at the office of the C.M.B., Caxton House, Westminster. The leaflet calls attention to the absolute importance of *early* medical treatment of uterine cancer, and the mistake of attributing irregular hæmorrhage to the menopause, and it strongly advises midwives who are consulted by patients suffering from such irregularities to avoid expressing any opinion of their own, but to send the inquirer to a properly qualified medical practitioner for examination.

The next meeting will be held on July 23rd. The penal cases will be heard on July 9th and 10th, at 2 p.m.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, June 5th, 1908.

The President, **Richard Lake**, F.R.C.S., in the Chair.

Dr. Andrew Elliott opened a discussion on

THE CAUSES OF UNCONSCIOUSNESS

by a paper dealing with the causes of insensibility and, secondarily, with the general methods of investigation which would be found of use. He emphasised the necessity of a clear idea of the various possible causes of unconsciousness in order that none might be overlooked, and suggested a tabulation of the possibilities based on a *memoria technica.*

Referring to the examination of an individual case, he urged a systematic method of procedure, by a scrutiny of the following points in succession:—(1) The history, if obtainable, of the case. (2) The general condition of the patient and the depth of the coma present. (3) Signs of injury, especially cranial fracture. (4) Any peculiarity in the breath. (5) The condition of the tongue and mouth. (6) The pulse, temperature and respiration. (7) Local paralyses or rigidities. (8) The general sensation. (9) The reflexes. (10) The eyes—(muscles, pupils, cornea, fundus). (11) The urine. (12) The stomach contents. And lastly, if necessary, an examination of the cerebro-spinal fluid, withdrawn by lumbar puncture.

Dr. A. E. Russell continued the discussion and commented on the unconsciousness of epilepsy, and pointed out that in some cases convulsions might be so slight as to escape notice, or even be absent. In some cases of hysterical attacks the diagnosis from epilepsy was not easy, especially in view of the frequent complete absence of knowledge by the patient of what had occurred during the attack; the possibility of some of these attacks being really the sequel of unrecognised *petit-mal* had also to be borne in mind.

As regards apoplexy—in children embolism, and in young adults syphilitic endarteritis had to be considered, whilst in older adults thrombosis from cerebral arterio-sclerosis and cerebral hæmorrhage were the chief factors. Thrombosis was more common than was usually suspected. The chief points in coming to a diagnosis were, the presence of premonitory slight and transient attacks, the frequent mildness of onset, and the presence of a low pressure pulse and dilated heart in cerebral thrombosis, as compared with the more violent onset, the deeper and more prolonged unconsciousness and the high blood pressure and hypertrophied heart, so commonly found in cases of cerebral hæmorrhage. The importance of accuracy of diagnosis was obvious in view of the different methods of treatment required in the two classes. The condition of uræmia was also considered. Catalepsy was a rare phenomenon, but did occasionally occur. The unconsciousness met with in men working in deep wells and the holds of ships was also referred to. Professor Haldane had shown that this was due to absorption of oxygen from the air, leaving an atmosphere composed in the main of nitrogen. The danger of this was that the patient did not, as a rule, recognise his danger, owing to the absence of marked dyspnœa or discomfort, and unconsciousness occurred very suddenly.

THE ASSOCIATION OF SCOTTISH MEDICAL DIPLOMATES.

Annual Meeting of the Association at 11, Chandos Street, London, W., on June 22nd.

The President, Dr. **David Walsh**, in the Chair.

The President, in presenting the 5th annual report of the Council for the past year, remarked that their attention had been again directed to matters of much importance to all who held a Scottish medical diploma. The Royal Colleges of Edinburgh and Glasgow had been once more approached with the suggestion that a membership qualification should be substituted for the present licentiateship conferred under the conjoint examination. There could be no doubt whatever that in many instances a Scotch licentiate was placed at a disadvantage in practice by comparison with the English diplomate who had obtained a membership qualification. The public naturally regarded a licentiate as something inferior to a member. Seeing that the Scotch diplomates were scattered throughout the United Kingdom the Scotch Colleges might naturally be expected to take an active interest in the matter. The Colleges might at a stroke of the pen either convert the existing license into a membership diploma, or add the desired membership qualification. From the circular sent out to Scottish diplomates some years ago by the Association it was evident that many licentiates felt keenly the disadvantage which they were placed by not having a membership qualification. The Association asked for the support of every Scotch diplomate in the United Kingdom in their renewed attempt to secure a Scotch membership equivalent to that granted in England. Another point in which the Association had moved was an attempt to remove the disability attached to Scotch qualifications in many provincial and most London hospitals. The Council had taken the important step of uniting with the Irish Graduates' Association in a strenuous attempt to remedy that injustice. Representations had been made to the boards and the governors of hospitals concerned, to the English, Scotch, and Irish Colleges, and to the Hospital Funds. This matter it was proposed to follow up vigorously through the forthcoming year.

As regards the finances of the Society, the Hon. Treasurer, Mr. Sydney Stephenson, was able to report at the end of the financial year a balance of £44. This satisfactory state of the resources of the Association was eminently encouraging. As time went by they hoped year by year to increase their roll of membership. The value of a Society of that kind lay to a great extent in the moral support afforded by the mere fact of co-operation in the defence of common interests. In the course of time there was every reason to hope that a large number of them would join the Association, especially if it could be shown that unceasing efforts were being made to establish the claims of Scottish diplomates to the equality of social and of professional opportunity, to which, as legally qualified members of distinguished schools, they were entitled.

The report was then adopted, and the following officers elected for the ensuing year:—President, Dr. Walsh (re-elected); Treasurer, Mr. Skene Keith; Secretary, Dr. I. Parsons.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, June 21st, 1908.

Chronic Appendicitis.

Paroxysmal vomiting deserves more than a passing notice. For a long time periodic vomiting was attributed either to uræmia, migraine, hysteria, or hepatic disease, but those surgeons who operate on many cases of appendicitis—Jalagnier, Broca, Rontier, Ricard, etc.—noticed the frequency of cyclic vomiting in the antecedents of their patients, and this in the majority of cases disappeared after removal of the appendix.

Consequently, this kind of vomiting in children should be regarded with suspicion, as generally it is a symptom of chronic appendicitis.

The intestine acts as badly as the stomach. Constipation is the rule, and its persistence should draw attention to the appendix. Sometimes, on the other hand, enteric diarrhœa is observed or entero-colitis. Frequently the children complain of colic after meals, and its repetition should awake suspicion. These pains are exaggerated under the influence of purgatives and enemas, but are attenuated by rest and diet.

In many cases the patient localises the pain, not on the right side of the abdomen, but around the umbilicus and in the epigastrium. In any case, too much importance should not be attributed to the exact seat of the pain, but every child complaining of suffering in the abdomen should be examined for chronic appendicitis.

Such are the principal symptoms presented by the digestive organs. The general aspect of these patients would lead to suppose the existence of heart disease or consumption; pallor, palpitations, oppression, wasting, but auscultation of the respective organs reveals nothing abnormal. Some children present a notable arrest in development. They do not grow nor gain strength, and seem to be under their age.

Local examination clears up any doubt as to the nature of the affection. The abdomen will be found supple and almost insensitive to the touch But if the fingers are pressed down in the MacBurney region a pain is felt which is not found to exist elsewhere. Sometimes a hard cord is felt rolling under the fingers which is probably the painful and inflamed appendix. At other times the mass is difficult to define, but would seem to be formed by the glands of the region.

The prognosis of chronic appendicitis in children is variable. No immediate danger exists, but an acute attack accompanied by peritonitis or perforation is always to be feared. Spontaneous cure is possible, but cannot be counted on. Frequently the chronic inflammation persists indefinitely even to adult age.

The treatment is both medical and surgical. A good diet should be prescribed, the patient should masticate well, eat little and slowly, prefer the vegetarian *régime* to any other, avoid all excesses, violent exercises, and constipation, etc. Such a *régime* has its value, and may for a time produce, more or less, prolonged relief, but in general the removal of the appendix is necessary.

While on the subject of appendicitis it may be interesting to state that in acute appendicitis, the temperature taken in the axilla is higher on the right side than on the left. In no other febrile affection has any such difference been remarked.

Thiosinamin and Fibrolysin.

Injections of either of these agents have been freely used in certain pathological conditions, and with, frequently, much benefit.

The affections amenable to the treatment are: Cicatricial retractions following burns; retraction of the palmar aponeurosis; chronic articular affections (in arthritis deformans prompt absorption of the articular tumefactions results; cessation of pain, improved function of the joints are satisfactory results in ankylosis); stricture of the œsophagus; stricture of the pylorus; stricture of the rectum and the urethra; chronic prostatitis; plastic induration of the penis; adherences of the pleura; aortic disease (improves the dyspnœa and lowers the tension); chronic catarrh of the middle ear, with ankylosis of the bones; diseases of the eye (leucoma following keratitis, adherences, cicatrix consecutive to syphilitic iritis); gynæcological affections (parametritis, adherences between the bladder and the intestine following the ablation of myoma, causing, for years, great pain in evacuation—radical cure by injections of fibrolysin).

Such are, up to the present, the results of injections of thiosinamin and fibrolysin. It is possible that these facts will be confirmed by other authors in the near future, when the treatment will be more generally applied.

AUSTRIA.

Vienna, June 21st, 1908.

Hydronephrosis.

Moszkowicz presented a female, æt. 20, from whom he had removed a large tumour from the region of the kidney. The patient came to hospital with all the symptoms of hydronephrosis, and for which she was operated on. When the region was opened two large swellings presented themselves with an enormously dilated pelvis, and the kidney itself atrophied. Two centimetres below the pelvis the ureter seemed to be tightly tied as if by a ligature. When carefully examined the artery and veins of the organ had formed a loop on the ureter and strangulated it. After these vessels were relieved the contents of the nephritic pelvis passed along the ureter into the bladder, and the tumour thereafter disappeared without any further operation.

Ekehorn said that in the whole literature on the subject only twenty-five cases could be discovered that had any similarity to the present case in tying up the ureter and producing hydronephrosis. From this example we may learn something by asking ourselves if hydronephrosis does not always depend upon some anomaly in the vascular supply. The presumption is in favour of separating the abnormal vessels, and relieving the nephropexia that is assumed to be present.

Latzko thought these small vessels could hardly be congenital, but probably rose from some inflammatory basis which he had often seen to be present in that region.

Albrecht could not accept these hypotheses as an explanation of the complications as he had met with a large number of cases of hydronephrosis in the post-mortem room where no abnormal vessels were present, and where no inflammation could have existed.

Taudler remarked that the upper part of the ureters in the fœtus and infants lay in folds, and it was a long time in after life before they were stretched. Again, when the relationship of the adventitia ureteris which runs along the inner sheath of the ureter is considered, it is not improbable that the folds at the upper end might form a loop that would involve the ureter, thus producing hydronephrosis.

Blum showed three preparations of sacs formed in the pelvis of kidneys with abnormal arteries entering. All the three cases had the same clinical phenomena during life of intermittent hydronephrosis, viz., painful attacks in the loins, polyuria intermitting with oliguria, pyuria, and a palpable painful swelling over the nephritic region. In all the three the abnormal vessels crossed the ureters, and formed loops that interfered with the free circulation in the ureter. Latzko remarked that the higher position of the kidneys and ureters in the fœtus favoured this folding at a later period, which would probably produce a temporary congestion of the organ followed by compression and subsequent hydronephrosis.

EUNUCHS.

Prigl presented two cases where castration had been performed at 25 and 27 years of age respectively. In both the real typical eunuch could be observed notwithstanding the lateness in life of castrating.

SOLITARY TUBERCLE.

Tertsch exhibited two cases of tubercle in the eye. The first was a tumour about the size of a nut in the upper part of the right eye apparently rising from the sclera as a light reddish swelling. Though the diagnosis of tubercle could be made it was not so easy to determine its origin, whether from conjunctiva, sclera or choroid. His own diagnosis was the sclera.

The other case was a fold of the conjunctiva, half-moon shaped under the lid at the inner angle of the eye about the size of a bean. The conjunctiva could be easily moved over the swelling which fluctuated on percussion, and looked like a dermoid.

Although both of the patients were perfectly healthy the destruction of the eyes was inevitable.

NEPHRECTOMY AND TUBERCLE.

Kapsammer brought forward a healthy looking patient from whom he had removed a tuberculous kidney which was shown under the microscope. He spoke in rapturous praise of phloridzin in the diagnosis of any functional lesion in the kidneys.

The operation was performed under local anæsthesia; tropa-cocain 0.10 of a grain injected into the lumbar region. In tuberculosis of the kidney chloroform is contra-indicated as it produces a toxic condition in the other; if tubercle be present in the lung we cannot use ether, therefore we are reduced to a local agent as in the present case.

Blum agreed with phloridzin in the diagnosis, but as to the local anæsthesia he differed. It is well-known that albuminuria lingers long in the healthy after lumbar injections, therefore a constitutional narcotic is safer than this local one.

Kapsammer thought that Blum was prejudiced against local anæsthesia. It was the stovain-adrenalin that produced the albuminuria and not tropa-cocain.

HUNGARY.

Budapest, June 21st, 1908.

At the last meeting of the Budapest Royal Society of Medicine Dr. Benedict read a paper on

HYPERÆSTHESIA FOLLOWING HEART DISEASE.

The author mentioned two kinds of pain which occur in association with diseases of the viscera, one of these arises locally, the other by way of irradiation. The irradiation of the pains takes place by the painful stimulus entering the grey substance of the cord through the sympathetic centre, where it comes into connection with the spinal nerves entering the cord at the same level, and so the pain is reflected to these nerves also; and as the insensibility and pain localisation of the skin and subcutaneous tissue are considerably greater than that of the viscera, we are prone, therefore, to consider first the pains felt in the area of irradiation, *i.e.*, in the spinal nerves. The criteria of irradiated pains are of three kinds: First, the patient feels them, not only over the diseased viscus, in the thorax or abdomen, but he also feels them in his back. Secondly, the most painful spots are also very sensitive to pressure. Among these the easiest noted are those described by Boas, which occur in connection with stomach diseases. Thirdly, the skin over the painful viscus is hyperæsthetic even to a superficial touch. The hyperæsthesia runs round the body in a semi-circular form, has more or less horizontal borders, and disappears in the same order. These hyperæsthetic areas were first studied by Head. Every area has its anterior and posterior maximal spot, which corresponds to the point where the patient feels the most severe, spontaneous pain. Head differentiated twelve dorsal, five lumbar, and five sacral sections.

A much more general irradiating symptom is hemialgia. Dr. Benedict had found in patients complaining of painful sensations, having either functional or organic heart disease, that the sensitive nerves of the left side from the supra-orbital region to the peritoneal region were very sensible to pressure. If the disease is situated to the right side, as, for instance, in aortic aneurysm, or in congested liver, the hemialgia affects the right side.

The author then analysed 180 cases in which he investigated the symptoms just described more accurately. These observations showed that in aortic diseases the pains in the shoulder and in the occipital region, and along the outer side of the arm are most characteristic, chiefly on the left side. The most affected section is here the cervical segment. The painful areas, corresponding to the root of the aorta and left ventricle, are found in the regions supplied from the first, second and third vertebræ, and on the inner side of the upper third of the left arm. In sixty cases he found pains —corresponding to bicuspid affections—in the dorsal segments (fifth to eighth vertebræ). The very characteristic head and thorax hyperalgesias are due rather to the stenosis than to insufficiency. In insufficiency of the right ventricle the congestion of the liver, and the pains caused thereby, predominate. According to Benedict, the results attained by this method of observation help us greatly in the diagnosis of heart disease.

Dr. Alexander Korányi mentions a case in which he was able to distinguish between aortic aneurysm and thoracic tumour merely by the aid of this method.

Dr. Lukàcs showed a case of

ENCEPHALOPATHIA INFANTILIS.

The patient suffered during dentition from a febrile disease, after which paralysis developed on the left side. This typical paralysis exists to-day. The patient became subject to a mild form of epilepsy and was imbecile. This disease has no characteristic name, but is described from its most prominent symptoms. The reason of this we must seek in the fact that the three symptoms mentioned participate in the disease in a very variable degree. Dr. Lukàcs recommends the term—largely used by the French physicians—"encephalopathia infantilis."

A CASE OF TRAUMATIC MUSCULAR PARALYSIS OF THE EYE.

Dr. Por showed a patient who sustained a blow on the left eyebrow from the shaft of a carriage. He could not open his eye, on account of the great swelling, for a week. When he was able to do so he complained of double vision in every direction. The restriction of the eye movements and the diplopia supported the assumption that the inferior rectus and external rectus muscles were paralysed. How this condition was caused he cannot for certain decide. He related this case only for the reason that traumatic muscle-paralyses are very rare.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

New Medical Officer of Health for Edinburgh.—The Town Council have appointed Dr. Maxwell Williamson, Chief Sanitary Inspector for the City, to this important office. Dr. Williamson has already served the city efficiently for 17 years, and his promotion is welcomed by a large circle of friends. He assisted the medical officer of health for six years from 1891, and acted as his substitute during his absence on leave. He has also temporarily occupied the position of medical superintendent of the fever hospital, and was appointed chief sanitary inspector in 1898. In this capacity he created a new department, and has acquired an intimate knowledge of the sanitary requirements of the city, as well as of the conditions of housing, food supply, overcrowding, etc., which will stand him in good stead in the performance of his new duties.

Association of Physicians of Great Britain and Ireland.—The second meeting of the association took place in Edinburgh on June 12th and 13th, and was attended by about 140 members. The scientific proceedings occupied two forenoon and two afternoon sittings, and among the numerous communications made were several of more than ordinary interest. The dinner, held in the Hall of the Royal College of Physicians on the evening of the 12th, was well attended. Sir Thomas Fraser, the President of the Association, occupied the chair, and Drs. G. A. Gibson and Herringham acted as croupiers. In connection with the meeting demonstrations of interesting cases were given in the Infirmary, Longmore, and Sick Children's Hospitals, and a pathological museum was got together for the occasion. The meeting was voted a great success by the members and guests who took part in it.

Edinburgh School for the Medical Education of Women.—The difficulties in which this school finds itself have not yet been resolved. At a recent conference between the University Court and the Association, the latter were unable to put forward any feasible scheme by which the expense which the introduction of mixed classes would bring upon the University could be met, nor were they in a position to show where they could obtain new premises. The situation has arisen through the sale of Minto House to a commercial body, having deprived the women's school of a home. There does not appear to be the slightest likelihood of the University admitting women to its class-rooms, and as the women cannot, apparently, get accommodation elsewhere, matters are more or less at a deadlock. On the question of the desirability of mixed classes two diametrically opposed opinions may be held, and it is not, perhaps, unnatural that those who favour the system of men and women being taught together should be inclined to use the situation which now exists as a lever to attain their desires. On the other hand, the majority of those who are sincerely interested in the future and efficiency of the Edinburgh Women's Medical School see in a scheme of mixed classes nothing but imperilment of its hitherto successful career. Unquestionably, if the Association sets about it energetically, new premises could be obtained, though doubtless at some temporary inconvenience, and it is to be hoped that steps in this direction will now be taken, seeing that the University is obdurate on the question of mixed classes, even when met with the "non-possumus" argument which has been to some extent adopted. It has been said that the refusal of the University to admit women will mean that students in the future will be driven to Glasgow instead of Edinburgh. Be this as it may, a large body of the Edinburgh teachers, though they would regret such a step, would rather have it take place than see women and men sitting side by side in the University. It is not uninteresting, also, to note that some of the women who actually went from Edinburgh to Glasgow have already returned to their old school—even, as we are informed to one of the classes about which more than any other complaints have been made.

Leith Hospital.—The directors of Leith Hospital have appointed Dr. Lindsay Milne to be Pathologist to the institution, vice Dr. Comrie, resigned.

BELFAST.

Annual Meeting of the Ulster Medical Society.—On Thursday last, June 18th, the annual meeting was held, the President, Dr. John McCaw, in the chair. The report and statement of accounts showed that the society continues in a flourishing state. The treasurer has a substantial balance in hand, but he pointed out that much of this would be required for painting the interior of the institute, in view of the expected visit of the British Medical Association to Belfast next year. The following officers were elected for the Session 1908-9:—President, Mr. T. S. Kirk, F.R.C.S.; vice-presidents, Dr. R. Reid (Whiteabbey) and Mr. R. J. Johnstone, F.R.C.S.; honorary secretary, Mr. Howard Stevenson, F.R.C.S.I.; literary secretary, Dr. Rankin; treasurer, Dr. Victor Fielden; librarian, Dr. Storey; council, Drs. Robert Allen, A. Fullerton, T. A. Davidson, Robert Hall, W. J. Maguire, and Gardner Robb, with the seven trustees, Dr. John Campbell, A. Dempsey, J. A. Lindsay, John McCaw, A. B. Mitchell, Joseph Nelson, and Cecil Shaw. At the close of the meeting the President provided tea, coffee, and cigars, and then presented the handsome silver cup which he had offered for competition among medical golfers during his term of office, and which was won by Dr. McLorinan.

Medical Golfing.—The golfing members of the profession have had a busy time of late, for besides playing for the McCaw Cup, referred to in the report of the Ulster Medical Society, and which is a special competition for this year only, there has been the play for the Lindsay Challenge Cup, played for annually. On Wednesday, 17th, thirty-two competitors turned up on the Newcastle (Co. Down) links and played in nine hole heats. The result was a draw between Captain Archer, R.A.M.C., and Dr. Bailey, who will play off the draw at an early date. The competitors were entertained to luncheon in the Club House by Mr. T. S. Kirk, the President-elect of the Ulster Medical Society.

LETTERS TO THE EDITOR.

CHRISTIAN SCIENCE AT THE PAN-ANGLICAN CONGRESS.

To the Editor of The Medical Press and Circular.

Sir,—A good deal of sense and a good deal more nonsense was talked on the subject of Christian Science at the Pan-Anglican Congress on Wednesday last. The sense came from those whose speeches implied that the first and essential step in dealing with disease is the making of an accurate diagnosis, discovering the true cause; distinguishing between morbid states due entirely to mental conditions, merely functional disorders capable of being influenced by mental states, distinct concrete pathological changes in organic structures, and effects brought about by reception into the system of definite *materies morbi*. The nonsense was talked by those who seemed to have vague ideas as to what is implied by pathology, who made no attempt at discrimination, scorned medical science, and looked upon diseases as distinct entities to be exorcised and driven out of the body by methods of mediæval thaumaturgy. This latter is the view of the Christian scientist pure and simple. He undertakes not only by religious influence to give peace of mind to the hysterical or hypochondriacal sufferer, which sometimes is quite possible, he also undertakes to "destroy and cast out" every disease, whatever its causation, whatever phase of morbid process it may have arrived at—a feat quite impossible. Every medical man is aware of the influence of the mind upon the body, and is constantly taking this factor into consideration in determining the nature of his cases, and in advising measures of treatment. The influence of religion may be as much called for as a change of climate, may constitute as legitimate a therapeutical instrument, but we cannot put an end to the action of natural forces by prayer or ritual; we cannot control morbid processes by supernatural means; we cannot, in short, cure disease by miracle. To profess to do this in the names of Christianity and science is both blasphemous and truly murderous, albeit, unfortunately, it is not recognised as criminal in the present state of our code, in which laws regulating the practice of medicine are, as we know, unfortunately, almost entirely lacking.

I am, Sir, yours truly,

ALIENIST.

THE DANGERS OF SPIRITISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—Whilst desiring in no wise to depreciate the laudable efforts of that most eloquent pulpit orator, Father Vaughan, to whom you refer in your annotation, nevertheless his counsel is more or less invalidated owing to his belief or acquiescence in *séances*. At any rate, he is reported as saying:—"No doubt many *séances* were frivolous enough; *others were very real indeed*." (The italics are my own.) and where did they come, were they the spirits and where did they come, were they the spirits of friends who once dwelt in the flesh? Were they the angels of God, or were they evil spirits from a land which none of us wished to know?" Now, Sir, it is obvious that so long as human nature is what it is, and until the human mind evolves to a higher degree of sanity, which, in spite of many drawbacks, we may hope at some distant date it will attain, I say it is obvious that teaching of this kind is certain to allure and fascinate many minds of a type who might be described as residing in the clouds, never happy unless on the look-out for something that never has existed nor can ever exist. We cannot be surprised if such as these, in spite of Father Vaughan's warning, and his own dire experience, should be attracted and led to pry into the research and literature of the subject, nor can we be further surprised that many, with the idea of having, say, a chat with their ancestors, would readily risk the chances of embracing or invoking the "unclean spirits," which to Father Vaughan appears problematic. Whilst so much is going on to eliminate physical disease, there is, unfortunately, no remedy to prevent the spread of pernicious and corrupting literature, which is as certain poison to the mind as contaminated milk is to the body. Nor is it easy to conceive (without interference in the freedom of public opinion), how any practical and legal method could be devised. But a short time ago an Anglican clergyman lent me for perusal a magazine of the occult science group, which might operate in different ways according to the jocularity or gravity of the individual concerned. However, with every semblance of solemnity, one of the articles opened with the following extraordinary serio-comic statement, which should be enough to initiate insane delusions in an illogical mind:—

"A certain amount of correspondence appeared in this magazine some months ago relative to the experiences that individuals had of the sensation of appearing to be outside their own bodies, and it would be interesting to know how far this experience is a common one."

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, June 19th, 1908.

MR. TROUTBECK AND THE PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some admirable remarks upon the above-named question leave no room for criticism by your ordinary readers. They can only express their approval of the able and forcible manner in which you have discused the main issues. I would, however, like to call attention to one aspect of the matter which is brought into view to-day (June 19th) by the letter in the *Times* from the President of the British Medical Association, Mr. Henry Davy. He points out that as far back as May, 1903, the Association, with other medical societies, brought to the notice of the Lord Chancellor, by memorandum and by deputation, the procedure of Mr. Troutbeck in conducting inquests. From that day to this nothing has been done; the abuses have been allowed to continue and to increase, in spite of renewed protest; and even now it is doubtful whether adequate attention will be given to the representations of individual practitioners or to those of organised bodies having the right to speak in the name of the profession. Let it be noted that the evils complained of are of more importance to the public than to the profession; the reason for the neglect seems really due to the fact that the evils have been exposed by medical men; such treatment is, at any rate, never meted out to other professions. With similar grievances how long would solicitors or barristers have to wait for redress? There exists hardly another recognised profession so powerless as the medical to concentrate its influence and make it felt. This is the aspect of the present question which I feel needs regarding as much as any. What are the reasons for the political impotence of our profession; what can be done to cure it?

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

June 19th, 1908.

THE DEPOPULATION OF FRANCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A Parliamentary Commission on depopulation is now at work in Paris. The birth-rate statistics, from the patriotic point of view, are becoming more and more alarming. Numerous schemes are being proposed to encourage families by remission of taxation, or by taxation of bachelors and childless married couples. Last year's figures show that the deaths exceeded the births by no less than 19,929, a phenomenon that has occurred only ten times during the nineteenth century, and then was due to epidemics or war, not as now to the deliberate practices of virtually the whole people in restricting the number of offspring by artificial means. Whatever the effects of this custom upon the evolution of the race, its effects in improving or deteriorating the physical and moral qualities of the individual citizen, a question into which we cannot enter now, the fact remains that the population of France stands fixed at about 39,000,000, whilst that of her hereditary enemy, Germany, amounts to nearly 64,000,000, and is increasing at the rate of nearly a million a year. Unless we are to suppose that the French Army is so superior in physique and morale to the German that the odds would make no difference, it is evident that in "a fight to a finish" the victory would rest with the the big battalions, with the Power whose numbers are the greater. The plain fact is that France without allies would be at the mercy of Germany. True patriotism in the French citizens would seem to consist in the rearing of a numerous progeny, but whatever the excuse, this service to the State is evidently looked upon as a sacrifice too great to be borne by a people who are yet never tired of proclaiming their devotion to their beloved fatherland.

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

OBITUARY.

BERTRAM ABRAHAMS, B.Sc., M.B.LOND., F.R.C.P.

WE regret to announce the death of Dr. Bertram Abrahams, on the 21st instant, at his residence in Welbeck Street, London, after a few days' illness. Deceased was educated medically at University College, where he distinguished himself in various departments, and where he held a scholarship. He obtained first-class honours at the intermediate Science and the final M.D. examinations of the University of London. At Westminster Hospital he held the important position of Assistant Physician and of Lecturer on Physiology. He also acted as examiner for Physiology in the Conjoint Board of the English Colleges. Dr. Abrahams has been cut off at an early period of a distinguished career. His death will be a loss to the profession generally, and will be keenly felt in the hospital to whose service the best part of his brief professional life has been devoted. Amongst other accomplishments may be mentioned his attainments as a linguist, and his brilliancy as a public speaker. For a long time it has been known by his friends that he has been in indifferent health, and the immediate cause of death was anuria from exposure. Deceased has left a widow and one child.

GARRETT HORDER, M.R.C.S.ENG., L.R.C.P.ED.

WE regret to announce the death of Dr. T. Garrett Horder, of Cardiff, on the 15th instant. He had been in ill-health for the past two years, and had been confined to his room for about five weeks. Dr. Horder was the son of the late Mr. William Horder, of Salisbury, and was born in July, 1843. He was educated at a private school at Tisbury and at the City of London School. Afterwards he took up medical study at Edinburgh. He took his diploma of M.R.C.S.Eng. in 1886, and L.R.C.P.Edin. in 1873. For several years he was medical officer to the National Sanatorium, Bournemouth, a hospital for consumptive patients, and when he left that institution he practised for some time in Lancashire. He came to Cardiff 32 years ago, and will be remembered in the city as a valuable public servant. Politically he was a Conservative, and, a staunch supporter of his party, was always ready to offer his services. Dr. Horder had been president of the Cardiff Medical Association, a member of the council of the Medical Defence Union, hon. secretary of the Hospital Reform Association, and joint hon. secretary of the ethical section of the British Medical Association, and his name was closely identified with the subject of hospital reform.

DR. WILLIAM McHARRY, OF BELFAST.

WIDESPREAD regret is felt in Belfast at the early death of Dr. William McHarry, of Grosvenor Lodge, Belfast, last week, the result of a sudden serious development in a hitherto unsuspected chronic Bright's disease. Dr. McHarry qualified in the Royal Colleges of Physicians and Surgeons, Edinburgh, in 1897, and on starting practice in Belfast soon attained a wide measure of popularity and success. In football and Masonic circles, as well as in medical, his company was always welcome, for not only was he remarkably genial and kind-hearted, but he had a great share of native wit. He was unmarried. His funeral, which took place on Monday, June 15th, was largely attended.

REVIEWS OF BOOKS.

MODERN OTOLOGY. (a)

WHILE according every praise to the authors for the success of their undertaking, we find fault with the dedication. The otologist will feel slighted that he has not been coupled with the "students and general practitioners of medicine," for the book, in its completeness, is as worthy of the attention of the former as of the latter. Drs. Barnhill and Wales aim at producing a book for students and general practitioners in which the following objects are kept in view:—(1) To modernise the subject of otology; (2) to correct certain traditional beliefs; (3) to advocate the earliest possible prophylaxis or treatment; (4) to emphasise the importance of thorough examination and definite diagnosis; and (5) to thoroughly illustrate the text; and they have succeeded, in our opinion, in producing a volume which is warranted to succeed on all these points.

The first three chapters are allotted to anatomy, physiology and bacteriology of the ear. The anatomical illustrations are admirable and selected with evident care, the text accompanying them being very clear. The physiology is brief, but ample. All that is known about the bacteriology of ear disease is contained in ten pages, all of which are scientifically interesting, but they do not help us along very much on practical lines. We are then taken through diseases of the auricle, external meatus, general examination, the influence of nasal and naso-pharyngeal diseases; then, by easy stages, on to acute middle-ear catarrh, acute mastoiditis, chronic suppurative otitis, chronic mastoiditis, its complications (intra and extra-cranial), chronic non-suppurative otitis media, diseases of the perceptive portions of the ear, concluding with a short chapter on deaf mutism. We like the sequence of disease adopted, which strikes us as most rational, and adds much to the facility with which we can follow the various stages of the diseases. This is most felt when we are reading about the suppurative otitis, which develops into acute mastoiditis, or, later on, into the chronic mastoiditis, there being no digressions made to deal with "dry catarrh," for example. We congratulate the authors on the success of their labours, for they have given to the medical profession a work admirably suited to the general practitioner. We can confidently recommend the book to specialists, as they will find the book of much interest, for the operations are most carefully and clearly described, down to the finer details, by an otologist of extensive practical experience. The illustrations, mostly photographic, and the general production are very excellent and deserving of high praise.

RETINOSCOPY. (a)

THIS little book of 63 pages, with 54 illustrations, has reached the present edition through the appreciation accorded the earlier ones by those who desired instruction on the subject of retinoscopy. It is to be concluded that this popularity has been won by the concise and clear manner in which the practical details of retinoscopy, as practised with a plane mirror at a metre distance, have been described and illustrated in the former editions. The present edition maintains this position in the fullest degree. One feels, however, in reading it that there is too much of the scientific side of this interesting subject omitted, and that the practical knowledge to be acquired is thereby robbed of much of its interest and thoroughness. It seems to us a pity that Dr. Thorington does not render this practical little book more complete by devoting some space to the theory of retinoscopy, for we feel that he is the man to make it clear to his readers, and that the practical knowledge acquired without a backing of theory is unsound and "cheap." Opinions are very divided on the subject of cycloplegics in retinoscopy. The author has no doubt, for he advises that the "patient *must* have his accommodation thoroughly relaxed with a reliable cycloplegic."

We noted an error on page 40, where it is represented that —1 added to +0.5 equals —1.5 instead of —0.5.

To the increasing number of general practitioners who are going in for refraction work we can recommend this book as one to be relied upon for the practical teaching afforded in its pages.

ROYAL LONDON OPHTHALMIC REPORTS. (b)

THIS number contains the following articles:—E. Nettleship on "Retinitis Pigmentosa and Allied Diseases" (continued); W. T. Hancock, "Hereditary Optic Atrophy"; George Coates, "Pathology of Coloboma of the Optic Nerve"; G. Coates, "Congenital Pigmentation of the Papilla"; M. L. Hepburn, "Visual Fields in Retinitis Pigmentosa"; M. S. Mayou, "Lachrymal Abscess in the New-Born"; J. H. McIlroy, "Sympathetic Ophthalmia: Some Anatomical Considerations, with Special Reference to the Occurrance of Plasma Cells"; Charles Goulden, "The Fate of Eyes that have been Submitted to the Operation of Extraction of a Foreign Body by the Electro-Magnet."

(a) "Principles and Practice of Modern Otology." By J. F. Barnhill, M.D., Professor of Otology, Indiana University, U.S.A., and E. de W. Wales, B.S., M.D., Associate Professor of Otology, Indiana University. Five hundred and sixty pages with 305 original illustrations. Philadelphia: W. B. Saunders Company. 1907.

(a) "Retinoscopy (or Shadow Test)." By James Thorington, A.M., M.D. Fifth Edition, revised and enlarged. London: Rebman.

(b) "Royal London Ophthalmic Hospital Reports." Edited by Wm. Lang, F.R.C.S. Vol. XVII., Part II., January, 1908. London: J. and A. Churchill. Price 5s.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT SURGICAL LITERATURE.

Ophthalmo-Tuberculin Reaction.—R. Mills (*Queen's Medical Quarterly*, April) gives his experience of 128 cases in which the ophthalmo-tuberculin reaction had been tried, and discusses fully its diagnostic value. He believes that, taken alone, it is a symptom upon which a definite diagnosis should not be based, notwithstanding the fact that several cases have been reported in which patients showing none of the usual signs of tuberculosis have reacted to this test, and have at a subsequent period developed tuberculous disease. With our present knowledge a reaction cannot be regarded as an absolute diagnostic symptom, but rather as confirmatory evidence of great value. Observations of the patient's pulse, temperature, weight, and other clinical symptoms may still leave the physician or surgeon in doubt. It is then that the ophthalmo-tuberculin reaction becomes a valuable factor in diagnosis. G.

The Treatment of Large Herniæ.—J. Hahn (*La Semaine Médicale*, March, 1908) says when herniæ become very large, they may lose their right of domicile in the abdomen. Their reduction, if they can be reduced at all, can only be accomplished at the price of a dangerous increase of the intra-abdominal pressure, as the abdominal cavity has become unable to accommodate the herniæ. In such cases an operation for the radical cure of such herniæ has a special gravity, not only from the mechanical difficulty of reducing the hernia, but also from the tendency for the over-distended abdomen to impede respiration, and produce a state of slow asphyxia, ending in cardiac failure. The patient is apt to exhibit increasing dyspnœa, cyanosis, with progressive feebleness of pulse, and often dies within two or three days after the operation. When the patient happens to be both elderly and fat, this risk is greatly increased. The author prepares such patients for operation in the following way:—The patient is allowed to eat and drink as much as he likes of a diet containing no fat, and very little meat. An hour after the two principal meals of the day, a sufficient quantity of a purgative mineral water is given to produce a liquid stool which removes most of the intestinal contents. This treatment is continued for eight days; it is then stopped for a few days, and resumed and continued until a sufficient reduction of the patient's abdominal fat has been accomplished to allow a partial reduction of the hernial contents. The patient is kept in bed with the feet raised rather higher than his head; taxis is tried two or three times a day for some fifteen to twenty minutes. The rupture may be gradually reduced in this way, and prevented from bursting out again by plaster strapping. In this way, by gradual stages, the whole hernial contents may be accommodated inside the abdomen without producing any signs of dyspnœa. A sufficient period must be allowed to elapse for the abdomen to get accustomed to its contents before a radical cure is performed. Where this plan has been followed, the results in the author's hands have been uniformly satisfactory. G.

Early Sitting Up after Laparotomy.—Chandler (*Albany Med. Annals*, February, 1908) treats all his laparotomies in the following way:—No matter how weak they are, they recover from the ether in the sitting posture, in which they are supported by a bed-rest. As a result, the nausea is usually slight. They are kept in this position for twelve hours, and then allowed to assume any position that is comfortable, but are encouraged to use the bed-rest as much as possible. On the third day, if they are strong, and in any case on the fourth day, the patient is allowed out of bed and put sitting in a chair. All patients are allowed to walk on the fifth day, and from that time on are up and walking about until they leave hospital, which they usually do from the tenth to the fourteenth day. The author, after the abdominal wound has been dressed, covers the dressing with a broad strip of zinc oxide plaster, except in cases where drainage is required. His experience of this method extends over 1,000 laparotomies, and the results have been most gratifying. It prevents phlebitis. The patient is not weakened by enforced rest, recoveries are better, hernia is less frequent, vomiting is prevented, and convalescence is shortened. G.

Pneumothorax and Posture: the Importance of the Abdominal Posture in Operations on the Pleura and Lungs.—Elsberg (*Med. Record,* May 23rd, 1908) forms his conclusions on this subject by experimental work on dogs. A dog on its back under deep anæsthesia will stand a small opening into his pleura well, but sudden heart failure or dyspnœa and death sometimes follow. With large openings typical expiratory dyspnœa results, the heart becomes irregular and weak, the anterior mediastinal septum bulges into the opening, and often ruptures, double pneumothorax or stoppage of the heart occurring. With the animal lying flat on its belly very different results were obtained, the dog surviving with even one half of the chest wall removed. Furthermore, if a dog on its back has violent dyspnœa, the breathing will often become quiet and regular again when turned on its belly, and get worse when turned on its back again. The author made some further experiments to elucidate the explanation of these phenomena. He observed that the anterior mediastinal septum is lax, flaps to and fro, bulges, and is apt to rupture when the pleura has been opened. The posterior mediastinal septum is much tougher, more fixed and tense. When the dog is on its back, the heart falls backwards, and bulging of the anterior septum is made more easy, interfering with the respiration of the sound lung. The author found that if before the pleura is opened with the dog on his back, the pericardium be stitched to the anterior chest wall, marked dyspnœa does not follow opening the pleura. If the stitch is cut and the heart falls backwards typical pneumothorax symptoms appear. Also with the dog on its belly and the pericardium stitched back pneumothorax symptoms occurred, which were relieved by cutting the stitch, and letting the heart fall forward. The author employs the prone position in all patients requiring operations necessitating opening of the pleural cavity. In this position operations on the lateral and posterior aspects of the thorax can be done with ease. The anæsthetic was not interfered with. In patients in whom the operation for empyema was done, it was noted that with only one exception the coughing and interference with breathing, regularly observed when the opening in the pleura is made for this effection, was entirely absent. S.

Thirty-One Cases of Congenital Dislocation of the Hip Reduced by Manipulation.—Abbott (*Med. Record*, May 23rd, 1908) records thirty-one cases treated by him. The ages of the patients varied from two to thirteen years, the greater number were females. Twenty-nine were unilateral, two bilateral. The operation performed was the same as that described by Lorenzo, with the exception that, in some cases, the plaster-of-Paris spica was extended below the knee, in order better to control the after position of the limb. In three cases weight traction was used preliminary to the reduction. The author advises early operation, stating that the development in a dislocated joint is much retarded, and that after reduction is made the whole limb grows in a normal manner. Preliminary traction lessens the amount of force necessary at the time of reduction, and should be employed in all older patients. If the two bilateral dislocations be considered as four unilateral, the author's results may be summed up as follows:—Total number of hips operated on 33; 22 or 66 per cent. normal; 9 or 27 per cent. anterior position; 2 or 6 per cent. complete failures. S.

Nine Cases of Fracture of the Carpal Scaphoid.—Ely (*Med. Record,* May 9th, 1908) reports nine cases, the diagnosis of which were confirmed by X-ray photographs. From these cases he draws the following conclusions: Fracture of the scaphoid is comparatively frequent, and is often mistaken for sprain of the wrist. It often escapes detection, and recovers without any treatment. It is usually caused by a fall on the extended hand. It may be caused by punching with the closed fist, or rarely by superflexion of the hand. The one important symptom is tenderness over the scaphoid on the dorsum of the wrist. All other classical symptoms of fracture may be absent, except pain on motion. If fracture be accompanied by dislocation of the semilunar, extension of the fingers, especially the middle, will be limited and painful. The prognosis of simple uncomplicated fracture is good, that of fracture with dislocation less favourable. A good treatment of simple fracture is immediate immobilisation. If the semilunar is dislocated a piece of the scaphoid often goes with it. The dislocated bone must be replaced, or if that is not possible, removed. S.

The Surgical Treatment of Alveolar Pulmonary Emphysema.—Goodman and Wachsmann (*Med. Record,* May 16th, 1908) report nine cases of resection of costal cartilages for the treatment of alveolar pulmonary emphysema. Four of these cases were their own, and five were collected from medical literature. The treatment depends on Freund's teaching that emphysema is the result, not the cause of barrel-shaped chest. Pathologically the costal cartilages are in a state of fibrillation with calcareous deposits, and are devoid of their normal elasticity. This prevents the proper excursions of the corresponding ribs. By removing or resecting the offending cartilages the proper functioning power of the chest may be restored. The cartilages of the second and third ribs of the right side are most frequently involved, but all may be involved, the first usually being last affected if involved at all. The authors have performed the operation even under local anæsthesia with good results. The following is a fairly typical history. Patient, æt. 50, had frequent asthmatic attacks. He had great dyspnœa, and the finger tips and mucous membranes were cyanotic. Respirations shallow, and chest rigid. The third, fourth, and fifth ribs on the right side was resected for about 2 cm. together with the anterior perichondrium. To prevent reformation of the cartilage the posterior layer of the perichondrium was dissected from its attachments, and reflected over and stitched to the stump of the corresponding rib. The third night following operation the patient was able to sleep quite comfortably, and cyanosis had disappeared. Chest expansion was increased from less than 2 cm. to 5 cm. Four weeks later the right second and left second and third cartilages were resected. Following this the chest expansion increased to 6 cm., and the vital capacity, before the second operation 1,800 c.c. increased to 2,700 c.c. The authors from their own experiences form the following conclusions: 1. Freund's operation is of great benefit in emphysema with a rigid dilated condition of the thorax. 2. When the costal cartilage is resected, the rib recedes immediately. 3. The ribs move so freely that the finger tip is distinctly squeezed when inserted between the sternum and the rib. 4. The lung visibly contracts. 5. Relief may be afforded by operating on one side. 6. The operation is not dangerous, and is not followed by shock. 7. Cardiac insufficiency, asthma, chronic bronchitis, and albuminaria, are not necessarily contraindications of the operation. 8. Patients are very gratified with the results. S.

MEDICAL NEWS IN BRIEF

Royal College of Surgeons of England.—Election of Examiners.

A MEETING of the Council of the Royal College of Surgeons was held last Thursday, Mr. H. Morris, President, being in the chair, when the following examiners were elected for the ensuing Collegiate year:—Board of Examiners in Anatomy and Physiology for the Fellowship:—Anatomy: W. McAdam Eccles, M.S.Lond., F.R.C.S.; F. G. Parsons, F.R.C.S.; Arthur Thomson, F.R.C.S.; A. H. Young, M.B., LL.D., F.R.C.S. Physiology: T. G. Brodie, M.D.Lond., F.R.S.; G. A. Buckmaster, M.D.Oxon.; C. F. Myers-Ward; W. H. Thompson, M.D., F.R.C.S. Elementary Biology: James P. Hill; T. W. Shore, M.D.Lond. Anatomy: W. H. Clayton Greene, M.B.Cantab., F.R.C.S.; Arthur Robinson, M.D.; William Wright, M.B., F.R.C.S. Physiology: Bertram L. Abrahams, M.B.Lond., F.R.C.P.; J. B. Leathes, M.B.Oxon., F.R.C.S. Midwifery: Hugh J. M. Playfair, M.D.Lond., M.R.C.P.; W. R. Pollock, M.D.Cantab., F.R.C.P.; J. H. Targett, M.B.Lond.; Walter W. H. Tate, M.D.Lond., F.R.C.P. Public Health (Part I.): Harold R. D. Spitta, M.D.; (Part II.), H. Timbrell Bulstrode, M.D.Cantab.

It was decided to send some suggestions to the Committee of the General Medical Council engaged in revising the British Pharmacopœia of 1898, the college having been invited to express their views to the committee. A letter was received from the President reporting the proceedings of the General Medical Council at their recent session, and the best thanks of the Council were given to him for his services as the representative of the college on that Council.

A small committee was appointed to report on the answers received from the Fellows and Members regarding the admission of women to examination for the diploma of the college. The President reported that he had undertaken to place a room in the college at the disposal of the authorities of the Imperial Cancer Research Fund for their annual meeting which would take place on July 14th, with the Duke of Bedford in the chair.

It was decided to recognise the Dreadnought Hospital, Greenwich, for the purposes of study required for the Diploma of Fellow. Laval University, Quebec, McGill University, Montreal, and the Italian Royal Universities were added to the list of Universities whose degrees are accepted, under certain conditions as qualifying for admission to the final examination for the Fellowship.

The list of candidates who were awarded the Fellowship Diploma at this meeting will be found under the heading of "Pass Lists."

The President reported that he had received a letter from the Director-General of the Survey Department of the Egyptian Government asking that facilities may be given to Dr. Elliot Smith and Dr. Wood Jones, of the Cairo Medical School, to carry out in the museum of the college an examination of a collection of material found in the course of excavations made in the Nile Valley, and representing the varied races of people who inhabited Nubia in ancient times. The Egyptian Government has offered to the museum of the college the collection of material which is sent over for the purpose of this comparative study. The President stated that he had informed the Director-General of the Egyptian Survey Department that facilities would be given Dr. Elliot Smith and Dr. Wood Jones to carry out their investigations in the manner suggested. The Council thereupon resolved that the Egyptian Government be informed that the Council would regard the collection of specimens as a most valuable addition to the museum, and would accept the collection with grateful thanks.

A letter was read from Mr. J. W. Batterham, F.R.C.S., reporting that Mr. Thomas Lambert Hinton, who became a member of the college in the year 1833, died at St. Leonards-on-Sea, on the 14th instant, at the advanced age of 100 years 45 days.

The Position of the Royal College of Surgeons and the Irish Universities Bill.

During the past week the Prime Minister received privately at the House of Commons a deputation from the Royal College of Surgeons in Ireland to ask him to consider in a sympathetic spirit the injurious effect likely to be produced on the College and its School by the Universities Bill as it stands. It was pointed out to Mr. Asquith that the medical school of the Royal College of Surgeons in Ireland enjoyed no State endowment, that such an endowment was to be given to the Cecilia Street Medical School, Dublin, and that the advantage thus given to the latter institution would prove ruinous to the former. The deputation also emphasised the popularity of the diploma of the Royal College of Surgeons in Ireland conjoined with that of the Royal College of Physicians. The injury to the medical school of the Royal College of Surgeons must react unfavourably on the College itself. Sir Edward Carson introduced the deputation, and supported its prayer. Mr. Lentaigne, President of the College, and Sir Henry Swanzy, ex-President, put the case on behalf of the College, and Sir William Collins, Sir John Batty Tuke, and Mr. Butcher, all, like Sir E. Carson, University representatives, asked the Prime Minister to meet them as favourably as possible. Mr. Asquith promised that the arguments laid before him should receive careful consideration.

In committee on the Bill on Friday last Mr. Butcher proposed an amendment giving the Commissioners under the Bill power to affiliate the School of the College to the new University. Mr. Birrell said that the College had not as yet asked to be affiliated, and that he did not know that they wished to be. The amendment was lost. Later Mr. Birrell indicated that his sympathies were in favour of the affiliation of the College.

Irish Graduates and the Scottish Medical Diplomates' Associations.

At a recent conjoint meeting of members of the Councils of the Irish Graduates and the Scottish Medical Diplomates' Associations, it was proposed by Sir Charles Cuffe, seconded by Mr. Sydney Stephenson, and carried unanimously:—"That this meeting of representatives of the Councils of the Scottish Medical Diplomates and Irish Medical Schools' and Graduates' Associations protest against the advertisement in the medical and lay press for the appointment of a surgeon to the Miller Hospital, Greenwich, whereby an unmerited slur is cast upon the Fellows of the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Surgeons of Ireland in excluding such Fellows from candidature for the appointment, although members and Fellows of the Colleges of Physicians of both countries are not so disqualified for appointments as physicians to this hospital."

A Tuberculosis Prevention Bill for Ireland.

The text has been issued of a Bill, which was introduced by Mr. Birrell a few days ago, to prevent the spread and provide for the treatment of tuberculosis in Ireland. The Bill is divided into four parts. Part I. deals with notification and disinfection and contains *inter alia* the following provisions:—

If any medical practitioner attending on any person becomes aware that that person is suffering from tuberculosis of any form, or at any stage, and in any circumstances prescribed by an Order of the Local Government Board under this section, the medical practitioner shall forthwith send to the medical officer of health of the district in which the patient is a certificate in the prescribed form and containing the prescribed particulars.

The Local Government Board may from time to time by Order prescribe the forms and stages of tuberculosis to which, and the circumstances in which, this section shall apply.

If any medical practitioner required by this section to send a certificate fails to send the certificate forthwith, he shall be liable on summary conviction to a penalty not exceeding forty shillings.

The sanitary authority shall pay to every medical practitioner for each certificate duly sent by him in relation to a patient in their district a fee of one shilling if the case occurs in an infirmary, public hospital, or workhouse, and a fee of two shillings and sixpence if the case occurs elsewhere.

Where the medical practitioner required by this section to send a certificate is himself the medical officer of health of the district, he shall be entitled to the fee to which he would be entitled if he were not such officer.

The Local Government Board may make regulations for carrying into effect the provisions of this section, and such regulations shall, among other matters, prescribe the form of certificate to be sent under this section and the particulars to be inserted therein, and shall provide for the proper custody of all certificates, and for securing that, so far as is, in the opinion of the Board, consistent with the public advantage, no publicity shall be given to any of the particulars contained in any such certificate.

Part II. deals with the establishment of hospitals and dispensaries for the treatment of tuberculosis, and provides that a County Council may, if they think fit, provide hospitals and dispensaries for the treatment of inhabitants of their county suffering from tuberculosis, and for that purpose may—(*a*) themselves establish and maintain such hospitals and dispensaries; or (*b*) enter into an agreement with any person having the management of any hospital or dispensary for the reception, maintenance, and treatment therein of any such inhabitants of their county as aforesaid.

Part III. contains sanitary provisions and provisions relating to lectures and to the distribution of information relating to tuberculosis. It contains the following provision amongst others:—

A sanitary authority may, with the approval of and subject to such conditions as may be prescribed by the Local Government Board, provide and pay for the delivery of public lectures within their district, and for the distribution of pamphlets, notices, and leaflets on subjects relating to tuberculosis, and may, with the like approval and subject to the like conditions, provide any drugs or appliances which would tend to prevent or check the spread of the disease.

A County Council may appoint for their county a bacteriologist, with such qualifications and at such remuneration as may be approved by the Local Government Board, for the examination of meat or milk or milk products, and of sputum or pathological specimens, and may, at their discretion, dismiss such bacteriologists.

Part IV. contains various "general" provisions, definitions, etc.

PASS LISTS.

Royal College of Surgeons of England—Fellowship Examination.

The following candidates having passed the Final Examinations for the Fellowship (all of whom were qualified in Medicine and Midwifery), received the Diploma of Fellow on Thursday last, June 18th:—

John J. Urwin, Capt. I.M.S., M.B.Glasg.; Archibald M. H. Gray, M.D.Lond.; Geoffrey S. Hett, M.B.Lond.; Clifford A. Moore, M.B.Lond.; Harold Rischbieth, L.R.C.P.; Hamilton Irving, M.B.Lond.; James G. Gibb, M.B.Durh.; Montague L. Hine, M.D.Lond.; Charles M. Page, M.B.Lond.; Robert Davies-Colley, L.R.C.P.; Donald W. Roy, M.B.Camb.; Samuel W. Daw, M.B.Lond.; Alexander Kinder, M.B.New Zeal.; Harold A. R. E. Unwin, M.B.Camb.; Claud H. S. Frankau, L.R.C.P.; George C. E. Simpson, M.B.Camb.; Wilfred W. Holtzmann, M.B.Camb.; Arthur R. Short, M.D.Lond. F. J. F. Barrington, George P. Mills, and Chas. H. Smith also passed, but have not attained the legal age of 25 years.

Trinity College, Dublin.

At Trinity Term, the following candidates passed the Examination for the Diploma in Public Health:—Part I.—George E. Nesbitt, Thomas O. Graham, Richard G. S. Gregg, William R. Galwey.

Part II.—George E. Nesbitt, John A. Pringle, William R. Galwey, Thomas O. Graham.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

THE AUSTRIAN TYROL AS A HEALTH RESORT.

The value of the mountainous province known as the Austrian Tyrol can hardly be over-estimated as a health resort. The air, even in mid-winter, is pure, mild and bracing. The valleys are sheltered in spite of their high altitude, and offer climatic conditions suitable to many maladies, such as anæmia, neurasthenia, heart disease and many early pulmonary conditions. The magnificent scenery should alone suffice to render this country one of the most popular of touring grounds. Special hotel advantages may be obtained for medical men and their families. Particulars may be obtained by application to the Editor of the Medical Press and Circular.

Fibroid.—We know of no such person. Of course, he is not on the Medical Register. Our judgment is that the less you have to do with him the better. "Systems" of that kind are generally synonymous for something much less desirable.

K., D., S. & Co., Ltd.—We are sorry we can say nothing in favour of the pamphlet, and fear it will do little to promote the cause of public morality. We do not see that it will tell any parent or schoomaster anything he does not know well already. The writing is clumsy; the ideas confused; and the "humour" in bad taste.

CHINA TEA.

To the Editor of The Medical Press and Circular.

Sir,—There seems to be a concerted action on the part of the chairmen of the numerous companies who deal in Indian and Ceylon teas to deplore that medical men "in their ignorance" recommend the use of China tea to their patients. It is quite clear that they (medical men) are disinterested in doing so, as many of their patients from dyspepsia owe their troubles to the modern fashion of drinking strong astringent teas at all hours of the day.

It is an interesting sidelight on the subject that a majority of the persons engaged in exploiting the produce of our dependencies *drink China tea themselves*, notwithstanding that it is prepared by hand labour, the highly-coloured details of which are revived from time to time when it is found that people of light and leading are not to be deterred from its use, to the great benefit of their digestions.

Yours truly,
The Secretary of the China Tea Association.
Chesterfield House, London, E.C.,

L.R.C.P.Lond.—The Institution about which you inquire is a quack concern, started some years ago by an individual who was struck off *The Register* for "infamous conduct." We are not surprised to hear that a patient of yours was "had," to use your expression; he is not the first by a long way. He would however, find the money would be disgorged if it were found to be his determination to bring the case into Court.

Meetings of the Societies, Lectures, &c.

Wednesday, June 24th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. M. White: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. J. W. Carr: The Treatment of Acute Pneumonia.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Skin (Dr. Meachen); Eye (Mr. Brooks).

Works by GEORGE HERSCHELL, M.D.Lond.

Third Edition. Demy 8vo. Price 5s. net, by post 5s. 4d.

INDIGESTION: The Diagnosis and Treatment of the Functional Derangements of the Stomach.

Just Published. Second Edition. Demy 8vo. Price 1s. 6d. net by post 1s. 9d.

THE DIAGNOSIS OF CANCER OF THE STOMACH, with Special Reference to its Recognition in an Early Stage.

London: H. J. Glaisher, 57 Wigmore Street, W.

NOW READY. SIXTH EDITION, 587 pages, with 249 Illustrations. Royal 8vo. Price 15s. net.

Diseases and Injuries of the Eye.

WITH THEIR MEDICAL AND SURGICAL TREATMENT.

By GEORGE LAWSON, F.R.C.S.

Revised and Re-written by ARNOLD LAWSON, F.R.C.S.

London: Smith, Elder & Co., 15 Waterloo Place, S.W.

Fourth Edition. Revised, with additional matter. Price 2s. 6d. net.

THE NATURE AND TREATMENT OF CANCER.

By JOHN A. SHAW-MACKENZIE, M.D.Lond.

"There is a charm as well as an attraction about this work, inasmuch as it deals with many hitherto but little known physiological processes. . . . How many practising physicians and surgeons, for example, ever heard of trypsin before the author brought it under the notice of the profession, and proved its therapeutic value, besides showing its action on glycogen?" ". . . Furthermore, in this edition, we are introduced to another ferment named 'erepsin' . . . and the author draws attention to its probable value in the treatment of cancer."—The Medical Press and Circular.

London: Bailliere, Tindall & Cox, 8 Henrietta Street, Covent Garden.
Dublin: Hanna & Neale, 18 Nassau Street.

SECOND EDITION, with Illustrations, royal 8vo, 10s. 6d.

The Treatment of Lateral Curvature OF THE SPINE.

By BERNARD ROTH, F.R.C.S.

"In speaking of the first edition we expressed the hope that this book would do something to check the unscientific and often disastrous treatment of lateral curvature of the spine by spinal supports and prolonged rest, and this new edition is even better calculated to show the good results which may be obtained in lateral curvature by posture and exercise."—LANCET.

"There can be no doubt that good work has been done by the author by his strong advocacy of the more rational method of treating lateral curvature of the spine by exercises."—British Medical Journal.

London: H. K. Lewis, 136 Gower Street, W.C.

By W. ARBUTHNOT LANE, M.S.

Cleft Palate and Hare Lip.

New Edition, in large clear type, demy 4to, 5s.

"Mr. Lane makes out a clear case for early and almost immediate operation. To sum up: Mr. Lane has absolutely proved his contention, and rendered it quite clear that early operation is the right course on every ground, developmental and otherwise; and, further, that delay in performing staphylorrhaphy until the third or sixth year is fraught with most harmful results, and should not be permitted."—*British Medical Journal*, Jan. 27th, 1906.

Operative Treatment of Fractures.

New Edition, uniform with above, 7s. 6d.

The Operative Treatment of Chronic Constipation.

New Edition, uniform with above, 2s. 6d.

The Medical Publishing Co., Ltd., 22½ Bartholomew Close, E.C.

By Sir JAMES SAWYER, M.D.Lond., F.R.C.P.,
Senior Consulting Physician to The Queen's Hospital.

JUST OUT. 2s. 6d. net, 8vo, cloth, pp. 104.

POINTS OF PRACTICE IN MALADIES of the HEART.

The Three Lumleian Lectures at the Royal College of Physicians, 1908.

Fourth Enlarged Edition. 3s. net, 8vo, cloth, pp. 227.

CONTRIBUTIONS TO PRACTICAL MEDICINE.

Contents—*Insomnia; Gastralgia; Lungs and Heart; Floating Kidney; Habitual Constipation; Intestinal Obstruction; Ung. Ranunc. Fic. in Piles; Eczema; Chorea; Phthisis; Medicated Lozenges; Inhalations in Asthma; Diabetic Diet, &c.*

"Conveying much practical information."—The Lancet.

1s. 3d. net, 8vo, cloth, pp. 66.

INSOMNIA: ITS CAUSES AND CURE.

Two Clinical Lectures.

"Indications for treatment excellent."—St. Thos. Hosp. Gaz.

Birmingham: CORNISH BROTHERS, Limited.

Fourth Edition. Pp. xii. + 622. With 281 Illustrations. Price 10s. 6d. net.

SEWILL'S DENTAL SURGERY,

Including Special Anatomy and Pathology. A Manual for Students and Practitioners.

Edited by W. J. ENGLAND, L.D.S.Eng.; and J. SEFTON SEWILL, L.R.C.P., M.R.C.S., L.D.S.Eng.

"A complete manual."—Brit. Med. Journal.
"Has the charm of lucidity."—The Lancet.

London: Bailliere, Tindall & Cox, 8 Henrietta Street, Covent Garden.
Dublin: Hanna & Neale, 18 Nassau Street.

Registered for Home and Foreign Transmission.

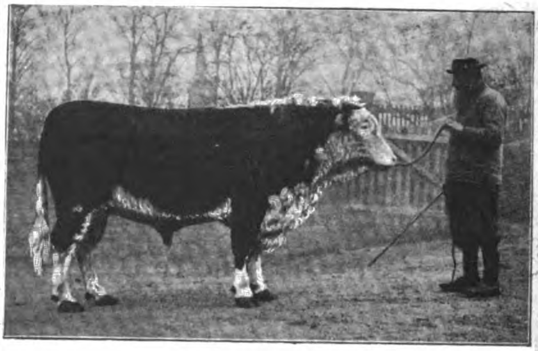
BUCHANAN'S

"BLACK
&
WHITE"

THE WHISKY OF WORLD WIDE REPUTE



Pedigree Hereford Bull "Viceroy," the latest addition to the magnificent stud animals on the "Lemco" farms.

A point to remember.

Medical men should remember that the words "Liebig's Extract" carry with them no guarantee of purity. Anything can be sold under that name.

Only by specifying "Lemco" can absolute purity be ensured.

The cattle used for "Lemco" are the progeny of fine British pedigree animals, and such precautions are taken in its manufacture that any deviation from its uniform purity and goodness is impossible.

Lemco

The original and only genuine Liebig Company's Extract of Beef.

THE TREATMENT OF

GASTRIC PAIN

whether due to Dyspepsia, Gastritis, or other cause.

EXPERT OPINION

as to the therapeutic value of

Bisedia

The **BRITISH MEDICAL JOURNAL** reports:—"A very attractive preparation, which can fairly be classed among the most elegant products of modern pharmacy."

THE LANCET says:—"We have employed this fluid in various cases of gastric derangement, simple and complicated. The preparation is decidedly elegant and possesses great therapeutic powers. In cases of gastric irritation the sedative effect is well marked."

A WELL-KNOWN SURGEON writes:—"I consider Bisedia an elegant and effective preparation for gastro-intestinal disturbance complicated with vomiting. In an experience of twenty years I have known no preparation to approach it in effect. It ought to be in the surgery of every practitioner."

This is no secret remedy, but a combination of Schacht's Pepsina Liquida (a really perfect Pepsine) with Schacht's Bismuth and Sedatives. Dose: ½ to 1 dr. diluted.

The formula is given on each label.

To be obtained of all the Wholesale Houses; or direct from

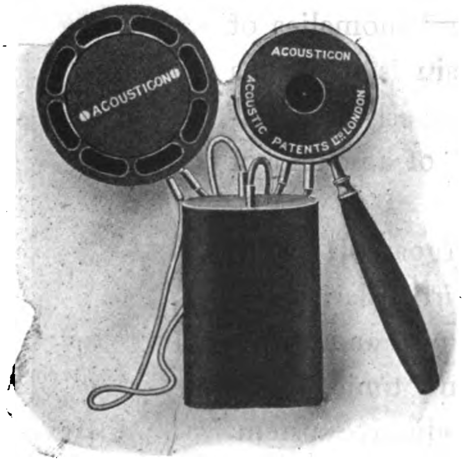
GILES, SCHACHT & CO., Clifton, Bristol.

BEWLEY & DRAPER'S
GINGER WINE

May be obtained of all Grocers and Wine Merchants.

Manufacturers:—BEWLEY & DRAPER, LIMITED, DUBLIN.

THE ACOUSTICON.



INSTRUMENT FOR THE DEAF.

This Instrument is not allied to Quackery in any form.

No claim is made for it that it cures deafness; it simply enables deaf people to hear ordinary conversation or music, which are at present denied to them

Its great value to patients who are beyond cure s now recognised by several leading London Aural Surgeons, and recommended by them to their patients.

It is extremely portable, but little seen when in use, will last a lifetime and costs complete in case, with two pocket batteries, £10 10s. 0d.

Sole Makers—ACOUSTIC PATENTS, LIMITED,

20 Bucklersbury, E.C., & 119 Victoria St., London, S.W.

NOTE.—This instrument will be submitted to any qualified practitioner at his residence on appointment.

V. O. C. B.

(VERY OLD CHAMPAGNE BRANDY.)

GUARANTEED 20 YEARS OLD.

BOTTLED IN COGNAC BY

BISQUIT, DUBOUCHÉ & CO.

Established A.D. 1819.

Obtainable from Distributing Wine Merchants, on application to the Wholesale Agents,

MERRITT, BIRD & CO., 11 Hart Street, Mark Lane, London, E.C.

CERTAIN as it is that a single acting cause can bring about any one of the several anomalies of menstruation, just so certain is it that a single remedial agent—if properly administered—can effect the relief of any one of those anomalies.

¶ The singular efficacy of Ergoapiol (Smith) in the various menstrual irregularities is manifestly due to its prompt and direct analgesic, antispasmodic and tonic action upon the entire female reproductive system.

¶ Ergoapiol (Smith) is of special, indeed extraordinary, value in such menstrual irregularities as *amenorrhea, dysmenorrhea, menorrhagia* and *metrorrhagia.*

¶ The creators of the preparation, the Martin H. Smith Company, of New York, will send samples and exhaustive literature, post paid, to any member of the medical profession.

¶ The same can also be procured from the Sole British Agents **Thomas Christy & Co.**, 4 to 12 Old Swan Lane, Upper Thames Street, London, E.C.

Hemaboloids

contains Iron combined with vegetable nucleo-proteids, closely approximating the natural food form, reinforced by Peptones, Bone Marrow Extract and Nuclein. It is in palatable, stable, non-irritating solution, does not constipate, and can be absorbed and assimilated by the most delicate stomach.

One tablespoonful contains the Iron equivalent of 20 Minims Tr. Ferri Chlor. Is indicated in all non-febrile Anemias, Adynamia after fevers, Brights Disease, Diabetes, Chronic Bronchitis and Emphysema, Cardiac disease, Neuralgias, Protracted Convalescence, etc.

IN THE TREATMENT OF

ANÆMIA, NEURASTHENIA, BRONCHITIS, INFLUENZA, PULMONARY TUBERCULOSIS, AND WASTING DISEASES OF CHILDHOOD, AND DURING CONVALESCENCE FROM EXHAUSTING DISEASES,

THE PHYSICIAN OF MANY YEARS' EXPERIENCE

KNOWS THAT, TO OBTAIN IMMEDIATE RESULTS, THERE IS NO REMEDY THAT POSSESSES THE POWER TO ALTER DISORDERED FUNCTIONS LIKE

"Fellows' Syrup of Hypophosphites."

MANY A TEXT-BOOK ON RESPIRATORY DISEASES SPECIFICALLY MENTIONS THIS PREPARATION AS BEING OF STERLING WORTH.

TRY IT, AND PROVE THESE FACTS.

SPECIAL NOTE.—Fellows' Syrup is never sold in bulk, but is dispensed in bottles containing 8 oz. and 15 oz.

THIS PREPARATION MAY BE OBTAINED AT ALL CHEMISTS AND PHARMACISTS THROUGHOUT THE UNITED KINGDOM.

BRAND'S
ESSENCE OF BEEF,
ALSO OF MUTTON, VEAL, and CHICKEN,
PREPARED from FINEST ENGLISH MEATS.
CAUTION.—BEWARE OF IMITATIONS.

BRAND & CO., Ltd., Mayfair, London, W

TAMAR INDIEN GRILLON.

A Laxative, Refreshing, and Medicated Fruit Lozenge.
VERY AGREEABLE TO TAKE, AND NEVER CAUSING IRRITATION.

Its physiological action assures the immediate relief and . . . effectual cure of . . . . CONSTIPATION,

HÆMORRHOIDS, BILE, HEADACHE, LOSS OF APPETITE, AND INTESTINAL OBSTRUCTIONS

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect— that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. Belin and Tardieu, who prescribe it constantly for the above complaints, and with the most marked success.

Wholesale—London: E. GRILLON, 67 Southwark Bridge Road, S.E.
Sold by all Chemists and Druggists, 2s. 6d. a box, stamp included.

ST. PATRICK'S HOSPITAL FOR MENTAL DISEASES.

THE GOVERNORS OF

ST. PATRICK'S HOSPITAL, DUBLIN

(FOUNDED BY DEAN SWIFT IN 1745),

Wish to announce that they have acquired a large property, in accordanbe with their Royal Charter (200 acres), and established a Private Asylum in connection with the Hospitals at Lucan. for the reception of patients of both sexes suffering from Mental Disease.

A NEW VILLA has been erected at Lucan for the accommodation of a limited number of gentlemen, and the entire establishment has been lighted by electricity.

The parent institution in Dublin continues its curative work, has undergone almost entire reconstruction, receives both male and female patients, and its recovery rate is very satisfactory. The Governors are anxious that the Medical Profession should be acquainted with the work of this historic institution, which has been devoted for over a century and a half to the reception and curative treatment of the insane of Ireland.

Urgent cases can be admitted by direct application to the Medical Superintendent.

For further particulars, forms of admission, &c., apply to the REGISTRAR, St. Patrick's Hospital, James Street, Dublin.

PRIVATE ASYLUMS,

Co. DUBLIN.

For Patients of the Upper Class suffering from Mental and Nervous Diseases, and the Abuse of Drugs. Established 1825.

HAMPSTEAD,
GLASNEVIN, FOR GENTLEMEN.

HIGHFIELD,
DRUMCONDRA, FOR LADIES.

Telephone No. 1082.

These Hospitals are built on the Villa System, and there are also Cottages on the demesne (154 acres), which is 100 feet above the sea-level, and commands an extensive view of the Dublin Mountains and Bay.

Voluntary Patients admitted without Medical Certificates,

For further information apply for illustrated prospectus, &c., to the Resident Medical Superintendents, Dr. HENRY MARCUS EUSTACE, Highfield, Drumcondra, or Dr. WILLIAM NEILSON EUSTACE, Hampstead, Glasnevin; or at the office, 41 Grafton Street, Dublin. Telephone 196. On Mondays, Wednesdays and Fridays, from 2 to 3 p.m.

THE ONLY ASEPTIC FEEDER MADE IS THE ROTUNDA FEEDING BOTTLE.

It is simple—only a pure rubber teat and bottle—no valve. It is safe—for it can be sterilised. It is cheap—6d.

Can be had wholesale from any Druggists' Sundry House, or from

LEONARD & CO., Chemists, Dublin & Belfast.

Leonard's Rotunda Tissue, 1/- per lb.

Leonard's Clinical Thermometers, 1/- each.

THE RETREAT PRIVATE ASYLUM,

Near ARMAGH.

(ESTABLISHED 1824.)

Licensed for the reception of ladies and gentlemen of the upper and middle classes suffering from

MENTAL AND NERVOUS DISEASES.

(Voluntary Boarders and Inebriates admitted.) This establishment has lately undergone many structural alterations and improvements, and the walks and grounds are extensive and picturesque.

Great care and attention are bestowed upon the patients, out-door and indoor games and regular carriage exercise being provided.

Golf links have recently been added.

For further information apply to the Medical Superintendent Dr. J. GOWER ALLEN, J.P., or Mr. JOSEPH ALLEN, Clonallen Armagh.

STEWART INSTITUTION

FOR IMBECILE CHILDREN, AND HOSPITAL FOR MENTAL DISEASES, Palmerston, Chapelizod, co. Dublin.

This institution receives imbecile children from all parts of Ireland free, or by partial payment, by election. Full payment cases at moderate rates. One vote for every 10s. 6d. subscribed annually. A life vote for £5 5s. donation.

The Hospital for Mental Diseases—a separate establishment—receives lady and gentleman patients from £50 per annum upwards, according to accommodation required. Management fully up-to-date in all particulars. Beautiful situation. Best modern sanitation. Fine demesne with necessary privacy. Voluntary boarders received.

Resident Medical Superintendent: Dr. F. E. Rainsford. All particulars from Secretary at Office, 40 Molesworth Street, Dublin.

DUBLIN.

FARNHAM HOUSE

For Gentlemen; MARYVILLE for Ladies.

AT FINGLAS, NEAR DUBLIN.

Private Hospitals for Patients of the Upper Classes
SUFFERING FROM

NEAR DUBLIN, FOR LADIES.

Established in 1857.

Telegraphic Address: "PROPRIETOR, VERVILLE, CLONTARF."

These Establishments are for the treatment and care of Ladies and Gentlemen suffering from mental disturbance or mental disease.

A limited number of Patients suffering from ailments arising out of the continuous abuse of alcohol or drugs are received as voluntary patients, without medical certificates.

A Catholic Chaplain visits regularly, and celebrates Mass on Sundays and Holy days.

Visiting Physician: Dr. BURKE SAVAGE, Rutland Square, Dublin. For further particulars, apply to Dr. LYNCH, or to J. J. MAGRATH, Superintendent.

Valentine's Meat-Juice

Where a **Powerful, Energetic, Non-Irritating, Rapid Blood-Building Nutrient** is required, in a **Concentrated Form, Easily Administered** and **Readily Tolerated** by the youngest child, when all other forms of food fail, **Valentine's Meat-Juice** is recommended by eminent medical authorities and extensively **used in Hospitals** devoted to the treatment of

Diseases of Children.

Thos. N. Vincent, M. D., *Visiting Physician St. Ann's Infant Asylum, Washington, D. C.:* "I have used Valentine's Meat-Juice in St. Ann's Infant Asylum, in the treatment of cases of Diarrhœa, incident to Teething in infants of delicate constitutions, and find it in every way satisfactory. It is easily assimilated, attended with no untoward symptoms and agrees in cases where other foods fail and when milk, prepared in any way used at present, also failed. I can testify also to its usefulness as a nutrient in Scarlet Fever and Measles."

H. H. Powell, M. D., *Professor of Obstetrics and Diseases of Children, Western Reserve University, Cleveland, Ohio:* "If I were asked in what class of cases Valentine's Meat-Juice has proved of most value in my hands, I should say Cholera Infantum and the Dysenteries of Children. Nutritious and stimulating, it is so agreeable to the taste as not to be refused by any Infant, however sick, and is so entirely assimilated as to leave nothing to irritate the lower bowels."

Dr. Raphael Raimondi, *Consulting Physician to the Montmartre Nurseries, Paris, France:* "I use Valentine's Meat-Juice with Nurslings eighteen months to two years old. These very weak Babies derive great benefit from the use of this tonic preparation. I give it to Debilitated Infants, after they are eighteen months old, in doses of one teaspoonful in thirty gramms of boiled water twice a day, and to be continued for a month."

VALENTINE'S
TRADE MARK
PREPARATION
NUTRIO PERME
MEAT JUICE.
The result of an Original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition (most important to life) are obtained in a state ready for immediate absorption.
DIRECTIONS.—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or moderately warm water. THE USE OF HOT WATER changes the character of the preparation.

Physicians are invited to send for brochures containing clinical reports.

Infantile Diarrhœa

During summer, Diarrhœa and kindred disorders among Infants are largely due to the use of infected cow's milk.

The "Allenburys" Milk Foods

are absolutely free from all harmful bacteria, and are made ready for use with boiled water.

The Foods are easily digested and assimilated, and contain both fat and proteids in similar relative proportions to those found in human milk. They are capable also of further modification, when desired, to suit the most delicate Infants from birth.

The 'Allenburys' Foods

The "Allenburys" Malted Food No 3
Allenburys Milk Food No 1
FOR THE FIRST 3 MONTHS
Allenburys Milk Food No 2
Allen & Hanburys LONDON
"ALLENBURYS" FEEDER

The "Allenburys" Milk Food No. 1.

FROM BIRTH TO 3 MONTHS.

This closely approximates in composition to human milk. It keeps thoroughly well, is easily prepared, the addition of hot water only being necessary.

The "Allenburys" Milk Food No. 2.

FROM 3 TO 6 MONTHS.

Is similar to the Milk Food No. 1, with the addition of a small amount of soluble phosphates and albuminoids.

The "Allenburys" Malted Food No. 3.

FROM 6 MONTHS AND UPWARDS

Is a partially digested farinaceous food, and requires the addition of boiled cow's milk and water.

A full descriptive pamphlet and samples will be sent on request.
